TENSION TOLERANCE

CHAIRMAN'S ADDRESS

HARRY S. GRADLE, M.D.

CHICAGO

It has been customary in the past for your chairman to discuss some one of the economic problems confronting our specialty or to present some scientific fact or observation. However, I have chosen to present for your consideration one phase of the glaucoma problem that is known but not adequately recognized; namely, the critical point in intra-ocular hypertension.

In view of the ever increasing blindness from glaucoma, it behooves us to exercise even more than usual care and caution in dealing with that disease. In a limited number of cases of compensated glaucoma, normal function of the eye may be preserved almost indefinitely without recourse to surgical intervention, and in other cases the use of surgical measures may be deferred many years before lack of control becomes evident. It goes without saying that, in an intelligent self-disciplined person, management of the disease without surgical procedure is preferable, provided the integrity of the eye is not thereby damaged.

Unfortunately, the majority of cases of compensated glaucoma are seen by the ophthalmologist only when the condition is fairly well advanced and surgical procedure is indicated without further quibble. This is particularly true with dispensary patients, who have universally the unfortunate tendency toward drifting until blindness is inevitable. It would be folly to try to control the disease in such instances by other than surgical measures and, as was so well emphasized in this section last year, time should not be lost before proceeding to the operation of choice.

Fortunately, in cases of compensated glaucoma time does not play the important role that it does when there is clinical evidence of a break in compensation. Evaluation of the situation without haste is permissible and the ophthalmic surgeon is not hurried into surgical intervention by the devastating swiftness of the disease. The fluctuation of intra-ocular tension under the influence of treatment may be studied and plotted graphically so that its influence on the functions of the eye can be determined. This leads to an inquiry as to what constitutes increased intra-ocular tension and what are the limits of normal intra-ocular tension. Obviously, no two eyes respond the same to variations in tension, and the endeavor to place a numerical evaluation on the upper limits of so-called normal tension is futile. It is possible to estimate that upper limit in each individual case only by a determination of whether the function of the eye deteriorates under the existing degree of intra-ocular

tension. Normal intra-ocular tension may therefore be defined as that degree of tension which the tissues of the eye are able to withstand without damage to function. And the final terms are dictated by the functions of the eye, the battleground between the ravaging destruction of increased intra-ocular tension on the one hand and the restraining influence of medical or surgical treatment on the other hand.

The function is obvious; namely, the act of vision. That act consists of three essential features in each eye: central field vision, peripheral field vision and central visual acuity. Consequently, any evaluation of the function of an eye must include accurate measurements of those three phases. Interestingly enough, there is a definite order of sensitivity of each aspect. Progressive loss of function due to hypertension will be manifest first by abnormalities in the central visual field, next by contractions of the peripheral visual field, and finally by a decrease in central visual acuity. With these facts in mind, it is evident that oft repeated estimations of the threefold aspects of vision are required to determine whether or not the function of the eye has suffered.

This is not the place to enter into a more or less theoretical discussion as to the reason for a pathologic increase in intra-ocular tension or as to the method whereby intra-ocular tension which is pathologically high for the eye in question produces the well known damage to function. This is rather a plea for the endeavor to ascertain whether intra-ocular tension that is commonly considered as above the upper tonometric limits of normal is really pathologic for the eye in question. In other words, what is the tension tolerance of the individual eye?

It is a well known fact that there are numerous instances of eyes in which the tonometric readings have ranged upward of 30 mm. of mercury (Schiotz scale) for years without damage to function in any one of its three aspects. It is also known that under the influence of emotion, physical stress or rarefied atmospheric conditions the tonometric tension will soar into the upper thirties and remain there for hours without damage to function. As opposed to that there are numerous cases on record of eyes whose functions have been lost with the typical picture of compensated glaucoma but in which the tonometric readings have never even approached the upper limits of the so-called normal. (This does not include the cases of Schnabel cavernous atrophy in which the loss of function and the clinical appearance are due to pressure by hardened arteries on the nerve trunks.)

These incidents are cited merely to show that intra-ocular tension which is damagingly high for one eye is still within the normal limits for another. This is just as true for an eye previous to medication as it is for one under the influence of miotics. Therefore, before pronouncing an intra-ocular tension pathologic it is necessary to determine whether that degree of tension is producing damage to the functions of the eye. If

repeated measurements show increasing pathologic abnormalities of the central field or contractions of the peripheral field or decreasing central visual acuity, then the tension tolerance of the eye has been exceeded and measures to decrease the existing tension must be instituted. Whether such measures should be of a medical or of a surgical character depends on the individual case and on the judgment of the ophthalmic surgeon. But the indication for the institution of such measures is the same in either instance; namely, that the eye cannot tolerate the degree of existent tension without damage to function.

There is nothing new in this line of thought or method of procedure, but the term tension tolerance is somewhat more comprehensive in its meaning as here expounded and emphasizes the idea that the indications for the medical or surgical lowering of intra-ocular tension are based on the influence of tension on function rather than on the mere existence of intra-ocular tension increased beyond the empirical numerical upper limit of so-called normal.

58 East Washington Street.

INDUSTRIAL ASPECTS OF EAR, NOSE AND THROAT PRACTICE

HAROLD A. FLETCHER, M.D.

SAN FRANCISCO

The development of state industrial accident commissions, marine industrial commissions, industrial accident insurance and public liability insurance has become so great that many private practitioners are becoming involved in this work, whereas a few years ago many refused to accept it. During the last twenty years I have had wide experience with this type of work. By far the greatest part of my industrial work has been acting in the capacity of referee or consultant, in cases which had previously been examined and treated, and reported by from one to ten or more different physicians. Patients have been sent either by the state industrial accident commissions or by the insurance carriers in California and neighboring states, or in some cases patients have come on their own initiative for an independent opinion.

I feel that the best way for me to approach this subject is to discuss critically the way this type of work has been handled as I have had an opportunity to observe it. I have had a great opportunity not only to see a large variety of cases and conditions but also to get a good insight into what other men think, how they approach a given problem and their strengths and their weaknesses.

Over this period of time I have become more and more impressed with the fact that a great many doctors have very little understanding or have actual misconceptions of the problems involved in this type of work. There has been some improvement during the last few years, but a good many men still make snap diagnoses and jump to conclusions and feel disgruntled when they have to furnish reasons for their conclusions. Some feel that a written opinion is unimportant or beneath their dignity and that no one has any right to ask for it. Some feel that the fees for such cases and reports do not warrant careful and painstaking examinations and thought. As far as fees are concerned, I have found

that, although they are below the average regular fees for private work of a similar nature, insurance companies and commissions are willing to allow a very fair return for good and able service. They are learning that cheap medicine is often the most expensive for them. Outlooks differ, but to me the most intriguing part of this work is the necessity of giving a written opinion with my name signed to it, knowing that some other specialist may not only disagree with me but have good reasons for doing so.

EXAMINER'S PROBLEM

There are three interested parties involved in each case: There is the injured patient, who usually and naturally wants as much compensation as he can obtain. There is the insurance carrier or self-insured employer who does not want to pay any more than he is legally responsible for. Lastly there is the industrial accident commission, which reviews the case, determines the responsibility, fixes the compensation if due and tells the insurance company or employer what amount the injured patient must be paid. The position of the ear, nose and throat specialist in relation to these three is to determine and report the facts and interpret them without fear or favor to any one of the interested parties.

To do this it is necessary to answer certain definite and fundamental questions in each individual case: 1. Is there a pathologic condition present? 2. Is the cause of the condition industrial or is it nonindustrial? 3. Does the condition create disability? 4. Are there other more probable existing or preexisting nonindustrial conditions which are contributing to or aggravating the condition, and is it necessary to correct these? 5. Can the condition be corrected? 6. Is the condition stationary or will it probably improve or get worse? 7. If stationary, what degree of disability exists, or, in other words, what has the patient lost that makes him less able than formerly to carry on his work? These questions should be faced honestly and answered as intelligently as the available facts and judgment permit.

One of my chief criticisms of many men doing this work is that they take sides in a certain case and allow prejudice to creep in. There is often a tendency for a consulting physician to try to build up a case as a lawyer would to win a case, hiding facts which hurt his side and unduly emphasizing points which will help to prove his side. I suppose that in some cases this is a natural reaction, but it should be fought against and suppressed, as in the end it almost always reacts to the physician's disadvantage and injures his reputation. It is more noticeable in those doing work more or less exclusively for large corporations and those doing public liability work whose expert testimony is readily available in medicolegal cases. It often surprises me that a doctor will assume an almost personal responsibility for an injury or the results of an injury when he should in no way have any personal feeling in the matter.

EXAMINER'S APPROACH

Another interesting and general aspect, which is of importance in this work, is the attitude and approach of the doctor toward the patient. One encounters all types of personalities and characters among these patients. There are the strong and the weak, the cowardly and the brave, the aggressive and the retiring; there are the honest and the dishonest, the chiselers and racketeers, and there are different racial elements and other psychologic factors. In general too there is the fear complex of loss of functions, loss of time from

work, loss of income with family responsibilities and dependents, the bitterness of the economic situation and bitterness and suspicion toward employer, insurance company and doctor. Then there are other groups with a neurotic predisposition and the group which has a low pain tolerance. A sympathetic and understanding approach to the injured patient is of greatest help in obtaining the best cooperation between physician and patient. Even in the face of obvious lying and malin-gering, and even in cases in which there is a tendency toward a clash of personalities between the physician and the patient, it is a wise doctor who does not press his own views or feelings on the patient during his examination. One must be careful not to jump at the conclusion that a patient is neurotic or hysterical or a slave to imaginary complaints till one has proved that there is no organic basis for them, and then one has to evaluate all the foregoing factors to arrive at the reasons for the patient's reactions. This means that a little knowledge of psychology must be applied to ear, nose and throat work in these cases. A little thoughtful, sympathetic understanding of these points on the part of the specialist has been the means of rehabilitating a great many patients, whereas examination by a doctor with a hard-boiled attitude would have done untold harm. On the other hand, certain types need and thrive on more brusque and hard-boiled tactics. A good deal of care and judgment is necessary to make a decision in a given case.

IMPORTANCE OF EARLY EXAMINATION

There is still prevalent a tendency on the part of general physicians and surgeons and insurance carriers to delay calling in a specialist, particularly in cases of multiple injuries and in those of head and skull injuries. This delay has often led to greater disabilities and difficulties later in fixing a fair compensation. Insurance carriers, as well as some general surgeons, are learning this and in larger centers have corrected this to a certain extent. In smaller communities where the services of specialists are not readily available the delay cannot be helped. The result of delay in not having a specialist examine and make notes on the case as soon as possible after the injury often leads to many difficulties later on. A true history is often obtainable soon after the accident when the patient and relatives wish to cooperate with the doctor to aid in recovery as soon as possible. Later, when acute symptoms have subsided and compensation factors have begun to work, the patient often colors the history so as to make it appear that preexisting conditions were caused by the accident. Examination made as soon as possible after the injury, with careful notes, are of greatest importance. A history of existing chronic sinus infection, chronic or recurrent aural discharge, previous loss of hearing and the like not only may have the greatest bearing on the immediate treatment but may later be of the greatest importance in evaluating disability.

A careful history and consideration of the mechanics and careful, accurate first examination notes of the injury, how it was caused and how it occurred should always be obtained when possible. This point is often neglected and at times assumes great medical as well as medicolegal importance. Recently a patient received a blow over the left eyebrow when he stepped in a hole in the floor while he was carrying one end of a sofa. The end of the upturned sofa leg, about $2\frac{1}{2}$ inches in diameter, struck him as he fell forward against it. A bruise was caused which was described by the general physician called in as being over half an inch to the

left of the midline. A few days later an acute frontal empyema of the right frontal sinus, maxillary and ethmoids developed. A local specialist operated on the frontal sinus externally and later, in consultation with another specialist from San Francisco, reoperated on it. Weeks later the patient claimed compensation for medical and hospital care and loss of working time on the basis of his injury. The local specialist said that the injury undoubtedly caused the frontal abscess. The San Francisco consultant refused to commit himself. The evidence, from the notes of the first physician, showed that the bruise was over the left frontal sinus at least one-half inch from the midline. The roentgenograms showed the dividing frontal septum to be in the midline. There was no involvement of the left frontal sinus. The mechanics as to how the blow occurred, the size of the object, the direction and severity of the blow, all taken together, decided the case against the patient in favor of the insurance carrier.

In many cases the specialist is asked to examine and give an opinion on the patient any time from months to years after an injury. Some insurance companies or their claims department see no reason why such a consultant should want to review the files and reports of the original accident and reports showing what happened between the time of the injury and the time the consultant is called in for an opinion. I have always insisted on these reports if in any way accessible, even when the site of the alleged injury is far from the head and neck. In one case a bilateral very marked deafness of the internal ear was claimed by a patient who had lost a leg and had an abdominal injury two years before. Two specialists had claimed that his deafness had nothing to do with his injury. The industrial accident commission sent him to me as referee. I obtained the hospital records after some delay and reluctance on the part of the self-insured corporation which employed the patient. In these I found that the patient had had two secondary hemorrhages almost to the point of exsanguination, had been under several ether anesthetics of long duration at this time and had complained to the nurses and doctors of severe tinnitus in both ears following these, and later of impaired hearing. Although the original injury did not directly cause the deafness, it was quite possible that a very severe hemorrhage combined with long anesthetics and general infection might have. So it is of the greatest importance that, before rendering an opinion or even making an examination, all available data be obtained by the consultant. If such data are not available, one must qualify one's opinion in certain cases.

METHOD OF EXAMINATION

As to the examination itself, it should be as complete as possible, and observations should be made with meticulous care, all the necessary methods and tests being used. Nothing should be taken for granted. Tests reported by previous examiners, unless one is sure of them, as in the case of x-ray and laboratory tests, should be checked and often rechecked. The examiner should always remember that when he signs his name to a report it may be subject to review by another specialist, who may not be his friend, and if the original examiner has missed a perforation in the ear drum or has not noted that a nasal septum has been previously operated on his competitor can make him look foolish.

In this regard I want to make one suggestion: A specialist should not try to make the other man look foolish or put him in an embarrassing position. He should be honest and frank in his differences of opinion and give his reasons but should not rub it in—it may

backfire! There are many cases in which honest differences of opinion can exist and in which at times both sides may be partly right and neither side completely right. There are many cases in which it is really a matter of opinion or experience as to whether the injury is the cause of the trouble or not, with no definite deciding factors present.

The foregoing has been concerned mostly with general considerations which I have found are often not understood by many doing this work. There is not space nor is it my purpose in this paper to name and describe a long list of industrial injuries. Rather it is to point out some of the important points and problems which in my experience have caused the most confusion and difficulty in evaluating.

INJURIES TO FACE, NOSE AND SINUSES

Injuries to the face, nose and sinuses I find are in general fairly well understood and treated. The cause and effects are perhaps more obvious, although even here one must not jump at conclusions. The time and method for the resetting and replacing of depressed and fractured bones, operations on sinuses for drainage or curettement, treatment of cosmetic defects and maxillary fractures involving the alveolar process and causing malocclusions of the teeth are all well known. Fractures involving the inner plate of the frontal sinuses or through the ethmoids and sphenoids must be carefully studied and watched and nothing must be done to disturb these regions until such time has elapsed that one is sure not to cause deeper intracranial infection unless complicating symptoms make procedures necessary. The question that often arises is this: Has a given moderate or mild injury over a sinus caused the sinus infection? This question is often hard to decide. Under normal conditions even a fairly marked fracture of the wall of the maxillary, frontal or ethmoids does not cause a sinus infection. There may be sterile blood clots which drain out, and that is all. On the other hand, when infection is found it is difficult to say that even a moderate contusion was not the initiating cause. Coincidental presence of an acute infection of the upper respiratory tract with injury to a sinus does not relieve the injury of a possible causal responsibility. Pre-existing chronic sinus infections may be lighted up by injury over one sinus, and if it was a chronic pansinus infection all the sinuses are apt to flare up. The difficulty is in the proper evaluation of what effect the injury had on the existing condition. In other cases shock, hemorrhage, exposure and fatigue following injuries to distant parts must be held as the indirect cause of acute exacerbations of chronic sinus infection and their complications. Sinus infection and obstructive nasal conditions following short or continuous exposure to certain kinds of smoke, gas fumes, chemical dusts and irritants are often hard to evaluate, owing to individual tolerance and predisposing or preexisting causes. Under this heading come the many allergic factors. Usually having the patient change his occupation or place of work will clear up the condition, but the patient often fights off his trouble to keep his job until his nose and sinuses are in such a state that long, expensive treatment is necessary. Irritants are occasionally self instilled in the nose by the patient, as was done by one of mine who, even when hospitalized, was caught snuffing pepper into his nose.

LOSS OF HEARING

The question of loss of hearing following injuries either directly to the ear or nearby parts or indirectly

from injury to distant parts I have found to be one of the most difficult problems to analyze and one which causes more confusion in the minds of other specialists than anything else. In many cases the problem of dizziness and vertigo is combined with the deafness and tinnitus, and the problems are overlapping.

There are, of course, the long lists of obvious direct injuries to the ears which give little trouble in diagnosing and evaluating. Foreign bodies, sparks, chemicals getting into or being forced into the ear, blows over the ear causing rupture of the drum, explosions causing an inner ear destruction—all these are usually easy to understand. The important question that always arises in the case of secondary otitis media is: Was the otitis media coincidental and the cause of the ear condition or was the otitis media caused by the injury? Careful questioning of the immediate train of symptoms following the injury and immediate careful examination of the external canal and ear for other signs of injury will often decide this point.

Not so obvious are those cases of injury to the skull involving either the region of the ear and mastoid or more distant parts, after which the patient claims loss of hearing and tinnitus due to his injury or claims vertigo as an incapacitating disability, or both. The two divisions of the inner ear, the cochlea and the labyrinth, are probably the two most often affected parts in head injuries. It has been my experience that there is more misconception of injuries to these parts than in any other field in this type of work. Of the two divisions, I have more trouble analyzing and evaluating the industrial loss of hearing to my own satisfaction than analyzing and evaluating the changes in vestibular function leading to vertigo and imbalance. Yet in reviewing many hundreds of reports of other specialists and neurologists I find them much more confused over the vestibular complaints and manifestations. The trouble seems to lie in a lack of knowledge as to what can happen to both divisions of the internal ear and their intracranial connections in the brain, what symptoms are caused and how to determine by tests whether such injuries or disturbances are present.

It used to be much more simple to decide these factors than it is today. There were certain dogmatic rules based on theory rather than facts which, if followed, made conclusions easy if false. I remember that after I read a paper¹ before this section in 1922 I was given a great working over by none other than Dr. George Shambaugh for stating that partial internal ear deafness could be caused by skull injuries and concussions. It was his view that the cochlea was either totally destroyed or remained free of injury in such cases and that the labyrinth was totally destroyed or remained free of trouble with the cochlea. Dr. Shambaugh and others may still feel the same way about it, but I think that most of us are convinced, not only from our clinical experience but from the wide observation of many on microscopic pathologic changes, backed up by the experimental work of others, that partial inner ear deafness and partial destruction of labyrinthine function can, and not uncommonly does, occur in various head injuries without complete destruction being caused. We are further convinced that the pathologic condition may be found in the inner ear itself, in the nerves or substance of the brain or in a combination of these locations. Space

1. Fletcher, H. A.: Determination of Disability as to Loss of Hearing and the Importance of Vertigo in Industrial Accident Cases, J. A. M. A. 79: 529 (Aug. 12) 1922.

does not permit of description of the pathology and mechanics of these disturbances, the location and type of fractures, the changes in the cochlea and labyrinth secondary to changes in circulation and cell structure, small hemorrhages into the perilymph spaces and in substances of the brain stem, commotion and shattering of the organ of Corti, secondary connective tissue formation, and the like. For reviews of the literature and references on this subject I particularly recommend the papers of Grove,² Linthicum³ and Schaller.⁴

Even greater than the confused knowledge as to what may happen in these injuries is the superficial knowledge as to what observations and tests are necessary to determine evidence of the pathologic condition and how to make them, as evidenced by the reports I have reviewed. The vestibular examinations are of the greatest importance in shedding light on these conditions; yet, to be of any value to the patient, the brain surgeon or neurologist or to the reviewing commission, they must be carefully carried out. Perfunctory and casual examinations are worse than none at all in many cases. The very careful observation of spontaneous nystagmus, past pointing and postural unbalance can be made only by repeated observations, good lighting conditions and care in elimination of outside factors not pertaining to the vestibular apparatus. The various tests of turning, head movement and caloric stimulation must be carefully and unhurriedly made and not made by just going through the motions.

I have found definite spontaneous vestibular nystagmus of a pathologic nature, or spontaneous past pointing, in so many cases in which it had been missed previously by other examiners that I feel sure that a great many men either do not understand the subject or, worse, make superficial observations. To me the spontaneous reactions may be of even greater importance than the induced reactions. Although not common, and somewhat differing from observations of other men doing this work well, I have noted quite a few patients with a spontaneous vertical nystagmus. Spontaneous past pointing, while definitely under some voluntary control of the patient, properly evaluated, has at times definite importance in judging a case.

As for the labyrinth tests themselves, there are men who confine themselves simply to turning the patient; other men confine themselves to mass caloric irrigations and turning tests; others use only the Kobrak test or the small measured amounts of water, paying particular attention to the finer gradations of latent time, character and duration of the induced reactions. I myself feel that one misses certain important signs unless one uses each of the methods in selected cases. In addition I frequently use the bi-aural mass irrigation in the two ears simultaneously, which often brings out an unbalance between the different canals that would otherwise be overlooked. There is one reaction with this test which I formerly considered as evidence of intracranial disturbance, and this is a vertical nystagmus upward after bi-aural caloric stimulation of the two horizontal canals simultaneously. As this occurs occasionally in normal patients who have been examined for demonstration purposes, I have long been suspicious that this reaction may have no pathologic significance, and recently I have

learned from Dr. Spiegel⁵ of Temple University that Brunner⁶ and others do not consider it pathologic. Regardless of the method used, careful description by the patient of what he means by his feeling of dizziness, and meticulously careful observation of spontaneous and induced reactions will decide the difference between a functional or an organic disturbance, and usually the difference between a peripheral and a central lesion. These are the points of importance to be determined. If the patient is shown to have normal labyrinthine reactions, he has in my opinion no organic cause for his complaint of vertigo. If he has a marked hypo-irritable labyrinth on one side and a normal or hyperactive labyrinth on the other, there is in my opinion a peripheral partial destruction of one labyrinth, and these patients are much more incapacitated for a longer time than if there was complete and total destruction on one side. If the patient presents signs such as spontaneous nystagmus, perverted induced reactions of nystagmus or past pointing, falling and the like, a disproportion between reactions of one set of canals as compared with the other, marked reduction in the normal general reactions of nausea, sweating, pallor, vomiting and the like, the indication is that the lesions are central in character, and this type of disturbance is apt to cause a more or less severe disability permanently or for a very long period of time. If the patient shows the uncomplicated aspects of a complete destruction of only one labyrinth, the prognosis is good for the clearing up of vertigo in from a few weeks to a few months.

As stated before, in my opinion the evaluation of disabilities from the vestibular or vertigo standpoint is much more clearly determined in relation to the accident or trauma than is that of disabilities of hearing. Many patients have a preexisting loss of hearing, either stationary or progressive, perhaps of such gradual onset or of such long duration that they have taken little note of the trouble. The hearing loss has not as yet constituted a disabling factor. One sees a large number of these in one's daily practice, with no history of trauma. If a patient suffers from vertigo he rushes to a doctor, but if he has a gradual loss of hearing he often stays away as long as he can. Of the two conditions, dizzy attacks are far more disabling than loss of hearing, and in this I agree with Ruttin,⁷ Rhese⁸ and others. Therefore, it is often very difficult to say that a patient claiming hearing loss after trauma to the head may not have had a preexisting loss to account for it.

Certain patients present no particular difficulties. The obvious transverse fracture of the pyramid with or without bleeding from the ears and complete destruction of the labyrinth and cochlea, the longitudinal fracture usually causing bleeding from the ear and possible evident disturbance and rupture of the drum and middle ear structures are cases in point. Those cases with marked unilateral or bilateral deafness following explosions through air concussion forces, also certain cases of head trauma in which definite coexisting evidence is found of disturbances of the labyrinth and vestibular pathways, may be fairly easily diagnosed correctly as attributable to the injury.

THE MALINGERER

But those cases of skull fracture not involving the temporal bone, or head injuries without fracture in which cerebral concussion symptoms were mild or absent but in which a loss of hearing due to the accident is later claimed, are often hard to evaluate or differentiate from preexisting hearing loss. It is in this group that one often finds the malingerer and the exaggerator, but one also finds honest loss of hearing which is the direct result of the accident. These cases often show evidence of previous middle ear processes which one is morally certain caused previous loss of hearing. It is also known that many nontraumatic private patients may have very advanced losses of hearing with no tangible evidence as to the cause. The hearing tests and audiometer curves in a traumatic case may be very similar to cases with no history of trauma. One point which has shown up consistently in my experience is the presence of markedly shortened bone conduction in most cases of skull fracture regardless of its location, and in many cases of only a mild or no loss of hearing by air conduction. This curtails the usefulness of bone conduction examination in many cases.

In cases in which hearing loss is claimed in only one ear there is the good ear for comparison. In my experience hearing defects in head injuries are far more often unilateral than bilateral, and the injured ear is more often on the side of the skull injury. If the ear in which a loss of hearing is claimed shows a different form of audiometer curve as compared with the ear in which no injury is claimed, it is presumptive evidence that the loss is traumatic. Bilateral loss of hearing, however, does occur but in my opinion rarely to the same degree in the two ears, except in the more profound losses found in basal fractures or severe cerebral concussions. When I find an almost equal bilateral loss of hearing with parallel audiometer curves of the usual abrupt or gradual high tone loss seen in nontraumatic cases and of only mild or moderate degree I am inclined to consider it nontraumatic in origin. It is conceivable that destruction of the same degree may occur through concussion transmitted through the two endolymphatic ducts, but I feel that this is rare.

Malingering or faking hearing loss is frequently encountered, and these cases are often missed. Many times patients cause suspicion by overacting their loss, but often suave actors with all the appearances of honesty are found malingering. The easiest to detect are those claiming complete or almost complete unilateral deafness. Many catch tests or confusion tests detect these cases, but the most conclusive test is the Stenger test. Malingering of marked bilateral deafness is often hard to prove, particularly in cases in which frequent tests have been made by many examiners. Discrepancies in repeated audiometer tests are often evidence of malingering, and audiometer tests should be carefully rechecked in most cases. Sometimes the only way to detect these discrepancies is for the insurance company to have a detective watch the patient.

COMPENSATION FOR LOSS OF HEARING

The rating of compensation for loss of hearing is interesting. The patient is usually compensated on the basis of what hearing he is reported by the ear specialist to have lost through the accident. It is also based on the impairment to his ability to carry on his work which has resulted. The duration of the compensation or total amount is based on the estimated time a willing patient would ordinarily take to rehabilitate

himself, either in his previous work or in taking up some other line of work more in keeping with his disability. The question arises as to what constitutes useful hearing. A patient doing certain kinds of labor may not be in any way incapacitated with a bilateral 25 per cent loss of hearing, whereas other types of work may necessitate almost normal hearing. In California the commission allows a 40 per cent disability for a 100 per cent bilateral loss of hearing, which means 160 weeks of compensation at 65 per cent of his previous average weekly wage. A 25 per cent loss of hearing in both ears is rated as a 10 per cent disability, which means forty weeks of compensation at the rate of 65 per cent of his previous average weekly wage. This is possibly too much in the case of a laborer and too little in the case of a mechanic whose work may need acute hearing. I think that otologists experienced in this work should make a group study of this aspect and attempt to arrive at a possibly more accurate standard method of rating hearing losses.

COMMENT

This presentation of industrial aspects of ear, nose and throat practice touches only on some of the broader problems as I have seen them. Many of these problems are not recognized by as many otologists as they should be. Many points are controversial, and I think that an effort should be made by the members of our specialty to give the subject the benefit of group study and discussion to clarify these controversial points as much as possible. The subject is becoming increasingly important and with the possibility of war on the horizon may become acutely so, because war disabilities and industrial disabilities have a great deal in common.

490 Post Street.

ABSTRACT OF DISCUSSION

Dr. W. E. Grove, Milwaukee: The line of practice to which the author refers is almost entirely medicolegal in character. Industrial medicine and surgery is a large and ever growing field. A doctor can and should handle these cases in a manner so efficient and so impartial that he retains the respect of the injured, the employer, the industrial commission and the courts. Industrial medicine and surgery should be done by a doctor with these qualifications. Dr. Fletcher is quite correct in saying that the most difficult question to evaluate after a head injury is the alleged loss of hearing. In the first place, after a head injury of any severity there is a clouding of the sensorium and of the hearing immediately following the injury which frequently clears up. If the patient is unscrupulous or neurotic, he may easily project this symptom into the future. Second, there are many cases in which the loss of hearing antedates the injury and the cause for such loss of hearing must be investigated. Third, the hearing defect after a head injury should fall into certain well established patterns, depending on the nature of the pathologic condition: a transverse fracture of the pyramid, a longitudinal fracture of the temporal bone, or a brain concussion with no demonstrable bone lesion. If the hearing defect does not fall into these patterns, one should be suspicious of trauma to the head as a causative factor. To estimate how much disability a hearing loss constitutes to the individual in general and to the individual in his own particular line of work is difficult. Complete loss of hearing in one ear is probably not as important to the individual as complete monocular loss of vision, and it is probably not as disabling as persistent vertigo. I cannot agree with the author that the loss of hearing affects only one ear in the majority of cases. In my experience the reverse is true, although I will admit that one ear is usually more involved than its fellow. The disabling effects of vertigo are variable, depending on its severity, its frequency and the nature of work engaged in and must be evaluated individually for each particular person and for each particular occupation. I agree with Dr. Fletcher that the spontaneous signs and symp-

toms of a deranged vestibular function are of more value in studying and evaluating the vertigo than induced labyrinthine reactions, but for a complete evaluation of the disabling effects of vertigo we must combine the psychologic characteristics of the patient, the complaints as offered, the spontaneous signs of vestibular derangement, the induced labyrinthine reactions and the occupation of the patient.

DR. H. A. KUHN, Hammond, Ind.: The otologist rarely knows anything of the previous hearing experience or the extent of injury by immediate examination of an injured employee. A phase of industrial otolaryngology which seems to be unclear is the otologic aspect, especially industrial deafness. Polokov, in his book *The Power Age*, states that "the labor specifications for a really modern industry are expressed in three terms: (1) sustained attention, (2) clear perception and (3) quick reaction, and only the most competent will be useful in industry." Speedups in rearmament will demand more competence of employees. Hence the problem of preventive otology should in the near future assume a very important position. During the last ten years this consciousness of accurate hearing in industry has seemed to come to the fore. Whereas it was formerly uncommon to have men from industrial plants complain of hearing difficulties or to have them rejected for employment unless the hearing difficulty was very marked, it is now quite common for them to notice that they do not hear the operation of machinery as accurately as formerly, and they are more frequently being rejected for hearing difficulties. In the future in otology just as in ophthalmology much more extended investigative work will be done in the employment divisions of modern industry. The problem of industrial deafness resolves itself into a matter of preventive medicine. After there has been injury to the end organ by repeated shocks and noises, we are at a loss to help the patient. Therefore, as otologists, we should practice more preventive measures. We should attempt to recognize these conditions in their early stages and we should try to do something to prevent workers from suffering repeated injuries to their ears. The only way to arrive at conclusions in this matter is to (1) record the hearing of all new employees, (2) at intervals recheck all those working and at shorter intervals all those subjected to persistent loud noises such as air hammers, and (3) make careful examinations of the ear, drums, nose and throat, investigate the family history and see to the moving of employees who show progressive hearing lesions to departments in which they are not subjected to otologic trauma, just as men subjected to a lead hazard are moved to completely free areas as soon as evidence of circulating lead is discovered. With the rearmament program going ahead full speed, the physical defectives interfere with the progress of that program. They must be kept from key points in modern mechanized industry by selectivity, and only by selectivity can we as medical men defeat this disintegrating influence on our national rearmament program.

DR. WALTER F. SCHALLER, San Francisco: A neurologist often leans heavily on the otologist, and I am going to take this occasion to testify my appreciation of the help I have often received from your specialty. Vertigo or dizziness as described by the patient often concern me much more than deafness. By complaint of "dizziness" the patient may mean a true vertigo, or he may mean a feeling of faintness or inability to walk in a straight line, all of which symptoms may be quite different in origin. The symptoms may be psychoneurotic in origin or due to an irreversible postconcussion state. In the psychoneurotic, whom I shall not discuss here, such symptoms are usually hysterical and due to a fixation of previous experience.

DR. REA E. ASHLEY, San Francisco: The need for more information of the type presented by Dr. Fletcher is great in this age of high industrialization with its incident development of industrial accident commissions, industrial accident insurance, public liability insurance and the various government insurance agencies. As time goes on, general medical men as well as specialists will be called on more frequently to render opinions on industrial injuries. Very little has appeared in the literature regarding this increasingly important subject and what has appeared has been fragmentary. It is desirable to have some standardization of methods of examination and correlation of symptoms to the pathologic condition as a guide for those of us

who see these cases only occasionally. The only method of obtaining such a guide is by the accumulation of the experience of those men who see great numbers of industrial injuries and the careful preparation of such data and statistics. May I offer the suggestion that the chairman of this section be requested to appoint a special committee to accumulate as many data as possible on the subject and from this information to suggest a *modus operandi* for the examination of head injuries as related to our specialty, together with an outline of any other information that may be helpful in drawing correct conclusions regarding the percentage of disability and the probable prognosis in these injury cases. The plan will necessarily have to be broad, since each case will present its own problems; but, if some base line can be established as a point from which to start, much will have been accomplished. The information will be of the utmost value to the general physician, the specialist, industrial accident commissions, insurance actuaries and the United States government.

DR. HAROLD A. FLETCHER, San Francisco: There are so many controversial angles which often arise in cases of head injuries that the medical profession, including specialists, is often put in the position of not knowing or understanding, and of not having any standards of agreement in these conditions. The legal profession, the industrial accident commissions and the lay public get the idea that we do not know what we are talking about. Lawyers use this confusion to trump up for their clients permanent disabilities from absurd alleged injuries. I have seen so much of this, arising from illogical controversial discussions in the medical reports I have reviewed, that I feel it high time that we as a group should come to some agreement on standards of computing industrial disabilities.

TREATMENT OF DISEASES OF THE THROAT

LYMAN G. RICHARDS, M.D.

BOSTON

The term "throat" as understood for purposes of this discussion is conveniently divisible into the mesopharynx and the hypopharynx. The mesopharynx is bounded posteriorly by the posterior pharyngeal wall, laterally by the lateral pharyngeal walls, superiorly by the nasopharynx and inferiorly by the larynx and upper pharyngeal end of the esophagus. Anteriorly it is bounded by the base of the tongue and by the open space directed toward the mouth. The chief organ within the hypopharynx is the larynx, bounded above by the mesopharyngeal space, posteriorly by the upper end of the esophagus, inferiorly by the trachea and anteriorly by the base of the tongue.

THE MESOPHARYNX

Within the mesopharynx lie the well known masses of lymphoid tissue, more or less symmetrically arranged to constitute Waldeyer's ring, which through their tendency to disease constitute such a large factor in the field of laryngology. Chief among these primary pathologic conditions affecting these lymphoid structures are the various infections divisible into acute and chronic. While the different masses of lymphoid tissue within the mesopharynx often share in irregular fashion in such infection, in a high percentage of cases the larger masses or faucial tonsils may be taken as representative of such infection and the treatment applied to them as the basic essential for other smaller areas with similar involvement. Thus simple acute follicular tonsillitis with its almost classic symptomatology is

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

representative of the commonest form of acute lymphoid infection. Its treatment consists of two parts, the systemic and the local. Patients suffering from acute tonsillitis should be kept in bed on a liquid or semisolid diet designed to relieve the almost constant dysphagia and permit assimilation of nourishment with as little discomfort as possible. I believe that a daily dosage of 15 or 20 grains (1-1.3 Gm.) of acetylsalicylic acid is helpful, supplemented, according to the discomfort, with codeine or even morphine, as designed to insure the patient as much general comfort as possible. I believe that properly constructed and properly applied hot moist external compresses of cotton sheet wadding saturated in saline or isotonic salt solution and closely applied around the patient's neck are definitely comforting in spite of the apparent objection that nothing is actually absorbed through the surface skin. If instead of saline solution some one of the proprietary preparations containing additional medicaments such as sodium perborate, sodium carbonate and small amounts of essential oils is utilized, the comfort of the patient is still further enhanced. With respect to internal therapy, I doubt greatly the efficacy of a gargle since the process of gargling approximates the tongue and soft palate in such a way as to keep any gargle material quite away from the tonsil surfaces. The sucking of various anesthetic lozenges containing such medications as chloroform, I believe, affords some comfort when the medication is swallowed, as does also the present popular aspirin. I like the application to the surface of the tonsil itself of 2 per cent silver nitrate, great care being taken that the drug comes in contact only with the tonsil surface and its crypt. I have almost equal enthusiasm for the local application of either 1 per cent aqueous methylene blue or gentian violet. Finally, I believe in hot saline or dextrose irrigations given with the patient's head well forward and by a nurse who understands the technic and who appreciates that the hotter such solutions are given the greater their efficacy. The aforementioned therapeutic measures should if possible be made a matter of daily routine. Finally, I believe that the use of an infra-red lamp, placed at a distance of 18 or 20 inches from the side of the patient's face and utilized for fifteen minutes three or four times a day, is a useful adjunct. In view of the self-limited nature of the disease, I cannot as yet bring myself to believe that routine use of sulfanilamide is either necessary or advantageous. My few experiences with it have led me to believe that, if given as commonly advocated, it frequently makes the patient more uncomfortable than the initial disease. In the absence of systemic complications or signs of systemic toxemia, I do not see indications for its use in simple acute tonsillitis.

The treatment of pharyngeal diphtheria, fortunately so increasingly infrequent, is quite obvious. Cultures should be taken of any suspicious membrane and, with the diagnosis of diphtheria returned from the laboratory, diphtheria antitoxin in adequate doses should at once be administered. The dosage may range from 5,000 to 30,000 units, according to the severity of the disease. Care must be taken in excluding possible sensitivity to serum by small intradermal injections of a single drop of antitoxin and observing the patient for local or systemic reactions.

Vincent's angina, affecting the mesopharynx and most commonly the tonsillar surfaces, is, owing to the anaer-

obic nature of the positive organism, best treated by the application of oxygen-bearing medication to the affected necrotic surface areas. Most satisfactory of these I still find 7 per cent chromic acid applied on a cotton tip swab two or three times a day. This should be supplemented by suitable measures for the attainment of as good oral hygiene as possible, such, for instance, as a mouth wash of sodium perborate or the commercial vinco or pharyngeal irrigations with a 1:10,000 solution of potassium permanganate. Strict attention should be given to the gums to prevent any spread of the infection to peridental areas. Local application of arsenicals such as arsphenamine is also a satisfactory form of treatment and in those rare instances in which the systemic signs with elevated temperature become evident, such arsenicals should also be given intravenously. Still more recently, but with less experience, I have been pleased with results obtained from the use of antimony and potassium tartrate (5 per cent). In view of the contagious nature of this condition, the patient is first isolated with particular attention to segregation of his food and eating utensils and other articles by which contamination may occur. So-called acute streptococcic sore throat, often epidemic in origin, and with inflammation more diffuse and less restricted to the tonsils themselves, has heretofore offered a most discouraging outlook from a therapeutic standpoint owing to the inability to achieve any specific therapy for this infection. The same measures designed to relieve discomfort in acute follicular tonsillitis are of course indicated here with the addition, particularly in the effort to combat systemic symptoms, of sulfanilamide, which is a most welcome specific agent in this disease. Variations in dosage and methods of its calculation are somewhat beyond the scope of this discussion, and the ever present possibility of complications and indications for withdrawal of the drug must always be kept in mind.

Peritonsillar Abscess or Quinsy Sore Throat.—By true peritonsillar abscess or quinsy sore throat is meant the localized collection of pus in the supratonsillar space bounded anteriorly by the upper portion of the anterior pillar, posteriorly by the posterior pillar and inferiorly by the superior pole of the tonsil. Any attempt at therapy is premised on the recognition of the presence of such a collection of pus to the point that surgical drainage is required. During the preliminary period in which an abscess may be forming, incision and drainage are contraindicated and the ideal therapy consists in relief of pain by sedation and by hot saline irrigations within the throat. Once existence of a peritonsillar abscess has been established by the clinical signs such as trismus, a point of maximum induration or suggestive fluctuation above the point of juncture of the anterior and posterior pillars, surgical drainage is indicated. This disease almost exclusively occurs in adults, seldom if ever in children; hence drainage is not only feasible but advisable under local anesthesia. In spite of exquisite local tenderness, it will be found that topical applications to the point of maximum induration of cocaine crystals will produce a satisfactory surface anesthesia. A long-handled Bard Parker knife with a No. 11 sharply angulated blade is then carried directly posterior at a point just above and median to the superior pole of the tonsils and directly through the soft palate tissue. It will be found that this incision produces only a minimum of pain. The knife blade is

carried inward a distance of from 1 to 1.5 cm. and then withdrawn. In nine times out of ten, if the clinical diagnosis has been made correctly and an abscess is present, withdrawal of the knife blade will be followed first by sharp bleeding but then immediately by a thin trickle of yellow pus, indicating contact with the abscess cavity. The blades of a slender, long-handled tonsil hemostat are then introduced through this incised track into the abscess cavity and quickly and vigorously opened. There will be an immediate gush of from 1 to 2 Gm. of pus, which the patient, with his head dependent over a basin, promptly expectorates. This divulsion of the track to the abscess is admittedly painful and I have yet to find any local anesthesia by which it can be avoided. I have tried the suggestion of anesthetizing the sphenopalatine ganglion in the nose but have not found the additional analgesia to compensate for the discomfort of the nasal procedure itself. Thereafter, hot saline irrigations for one or two days following incision will almost always lead to rapid subsidence of inflammation and prompt relief of the patient with only infrequent necessity of separating the wound edges or dealing with any adequate or impeded drainage. Subsequent tonsillectomy, particularly in the face of one or more attacks of peritonsillar abscess, is, I believe, clearly indicated. Failure on attempted incision to reach such a peritonsillar abscess should lead to abandonment of further attempts to probe hither and yon in an effort to find it. Observation and supportive treatment with sedatives and external and internal heat may be followed by a second and more successful attempt, provided the patient has not sought help from other sources.

Acute Pharyngitis.—Acute pharyngitis with congestion and inflammation of the posterior pharyngeal wall, oftentimes with enlargement of the small follicular lymph nodes scattered about on its surface, is a common complaint, particularly by patients who have undergone a previous tonsillectomy. Its present treatment is far from satisfactory, and the number and variety of remedies advocated bear witness to the lack of success of any specific remedy. I have as yet found nothing superior to periodic applications to the entire posterior pharyngeal wall of 3 to 5 per cent silver nitrate applied with a cotton tipped swab. Gargles are useless but I believe that patients frequently derive much comfort from a simple home remedy consisting of an instillation, through the nostrils, of a combination of sodium chloride, sodium perborate and sodium carbonate which, if the head is held in the proper position, will strike against the entire posterior pharyngeal wall and, by its astringent action, afford the patient considerable relief. This position can be satisfactorily assumed only when the patient sits in a chair with the base of his spine well away from the back of the chair and with the head so extended that the medicine dropper is in a perpendicular plane. From a half to three fourths of a medicine dropper of the mixture is instilled every one to three hours until relief is achieved. Hot saline or dextrose irrigations are also of some value, though there is less likelihood that they will touch the region of most acute sensitivity, which is usually behind the soft palate on the upper portion of the posterior pharyngeal wall. External compresses as described for acute tonsillitis are also a valuable adjunct, as is the infra-red lamp. Needless to say, the customary generalized supportive measures should be utilized in this condition.

Retropharyngeal Abscess.—The treatment of acute retropharyngeal abscess is essentially a surgical drainage of the abscess. This can obviously be achieved only if a correct diagnosis has been made, a matter not quite as simple as is often believed to be the case, owing to the fact that the abscess is only infrequently directly visible on simple inspection of the throat. So bizarre are the symptoms of retropharyngeal abscess and so frequently are they due to other unrelated conditions that one must exercise all one's diagnostic acumen in order to establish the existence of this condition. It was formerly the custom to drain such abscesses, almost always in infants and children under 3 years of age, with the patient in the upright position, held in the arms of a nurse, and with the physician palpating the abscess with the left index finger carried into the throat or back of the tongue. The knife held in the right hand was then passed along the left index finger and through the anterior wall of the abscess, the patient being then inverted and the evacuated pus allowed to drain out of the mouth. I believe this method is now outmoded and that such drainage without the aid of direct vision is not only unsatisfactory but at times dangerous. I prefer drainage with the patient in the supine position, the head extended somewhat over the end of the table and held in an assistant's hand with the operator sitting at the patient's head, facing his feet. The tongue is elevated by means of an angulated tongue depressor held in the same manner as one would hold a laryngoscope, with direct illumination of the posterior pharyngeal wall with a headlight or with a head mirror. With the anterior wall of the abscess thus exposed, even if located almost behind the larynx, a long-handled knife can be passed directly through it and into the abscess cavity. The presence of pus is at once manifested by a trickle of yellow fluid from the point of incision, thus permitting slow deflation and aspiration of the cavity with suction without escape of fluid into the lower airways. With final emptying of the major part of the abscess cavity, the long-handled hemostat is used to divulge the edges of the wound in much the same manner as in the case of a peritonsillar abscess. This will usually suffice to maintain ample drainage until the abscess cavity has healed and it is rarely necessary to perform secondary incision or drainage. This procedure is particularly useful when the abscess lies at such a low level that it can scarcely be felt with a palpating finger carried through the mouth and over the back of the tongue. Any surgical procedure carried out under direct vision without the necessity for suddenly inverting the patient and with uncertainty as to whether or not the abscess cavity has actually been opened is certainly preferable in my opinion. In this connection it is important to bear in mind the rare but ever present possibility of secondary hemorrhage in connection with retropharyngeal abscess. Such hemorrhages usually occur through extension of the infection in the region of the abscess to the internal carotid artery, with the formation of a pseudo-aneurysm which, periodically weakening the vessel wall, permits intermittent and massive hemorrhages from the throat. Once such a hemorrhage has occurred with temporary cessation it is the part of wisdom to proceed at once with ligation of at least the common carotid and possibly also of the external carotid artery. Ligation of the common carotid artery alone, readily picked up just behind and internal to the anterior

border of the sternomastoid muscle, may be sufficient to check such hemorrhage although it is still possible for blood, by collateral circulation, to descend by way of the external carotid artery and up the internal. If, after ligation of the common carotid, further bleeding occurs, the external may be ligated in the same manner. Ligation of the common carotid alone has the advantage that some blood is still permitted to reach the brain and in this manner it may be possible to avoid the unpleasant cerebral complications incident to cutting off the circulation by way of the internal carotid artery completely. Statistics clearly show that neglect of such a warning primary hemorrhage incident to a retropharyngeal abscess is fraught with the greatest risk to the patient's life.

CHRONIC INFECTIONS OF THE MESOPHARYNX

1. *Tonsillitis*.—There is still no unanimity of clinical opinion as to exactly what constitutes chronic tonsillitis. A history of previous acute attacks and evidence of surface irregularity with scarification of crypts and with hypertrophic or atrophic changes in the lymphoid structures usually are interpreted as evidence of clinical chronicity. The enlargement of adjacent cervical glands, symptoms of toxic absorption and local signs of irritation and vascular congestion are accessory factors which lead to this diagnosis. Once this state of chronicity is definitely established as far as possible, it does not seem to me that any of the palliative forms of therapy such as the various local applications, suction and vacuum cleaning of the tonsil can have much more than psychologic effect. On this basis tonsillectomy appears to be the logical procedure in all but those cases in which surgery is definitely contraindicated, under either general or local anesthesia, because of other factors in the patient's general condition. Operative technic is clearly beyond the scope of this discussion. Suffice it to say that my own preference is for complete surgical excision rather than for periodic diathermic removal of portions of the tonsil with the obvious disadvantages which attend this form of surgery. Where such evidence of chronic infection is found or thought to be due to the tubercle bacillus, tonsillar removal is all the more logical and necessary. Enlargement, induration and fibrosis of a tonsil accompanied by associated lymphadenitis must always bring to mind the possibility of a syphilitic origin. It is quite obvious that where this diagnosis is substantiated by serologic examination or even by microscopic examination of a small section of tissue removed by biopsy, the treatment is that for generalized syphilis in other parts of the body. Surgery would, in my opinion, be contraindicated.

Chronic Pharyngitis.—Chronic low grade inflammation of the posterior pharyngeal wall, both the lower portion visible anteriorly in the mouth and that higher up behind the soft palate, may be provocative of one of the laryngologist's greatest therapeutic dilemmas. Often there is objectively but little sign of pathologic change and only the insistence of the patient leads to attempts to apply any treatment at all. Enlarged local masses of lymphoid tissue can frequently be removed under local anesthesia with punch forceps or lightly coagulated with the actual cautery or diathermy. Application of various astringents such as silver nitrate or a 1:6 combination of iodine and glycerin if applied often and vigorously enough will sometimes effect a cure. More recently I have in several instances found multiple

small doses of x-rays effective in this condition. I have also had some apparent success with the prescription of an iodine preparation known as lipoiodine, which is taken daily for two or three weeks. Assurance of good bowel elimination, avoidance of cold air in the sleeping room at night, attention to adequate vitamin intake, especially with regard to vitamins A and D, and some consideration of disturbed metabolism requiring thyroid must all be given consideration in chronic pharyngitis. Particularly should an investigation be made of the nose and sinuses lest it be proved later on that a persistent discharge from these, running over the posterior pharyngeal wall, is provoking a constant irritation in this region. Not infrequently the process of atrophic rhinitis may extend to the posterior pharyngeal wall and give rise to the typical dry, glazed crusting on this surface. The present enthusiasm for estrogenic substances in treatment of this condition in the nose is likewise justifiable in the nasopharynx, and topical applications of such drugs as theelin have in my hands been quite successful in improving the general tone and vascularity of the posterior pharyngeal wall.

Foreign Bodies in the Mesopharynx.—The lodgment in the mesopharynx, either at the pharyngeal end of the esophagus in one or the other of the pyriform sinuses or between the epiglottis and the base of the tongue, is a clear indication for the removal of the intruder as the logical therapeutic procedure. Not infrequently this can be managed by means of thorough cocaineization of the entire pharyngeal region with 5 to 10 per cent cocaine, applied I believe most efficaciously with a camel's hair brush, and the utilization of a laryngeal mirror in order to visualize the foreign body. Where the latter consists of a thin sliver of chicken bone or fish bone clearly visible in the mirror, it can frequently be easily removed indirectly by means of a curved grasping forceps which, viewed in the mirror, can grasp the foreign body and effect its removal. If simple measures are not immediately effective, if the foreign body proves in any way to be impacted or removal is likely to result in any laryngeal trauma, such indirect methods should at once be abandoned and preparations made for proper endoscopic removal under direct vision. The technic for such operative measures is, I assume, beyond this present consideration of therapy.

Malignant Disease of the Mesopharynx.—Microscopic biopsy is the only reliable method of accurate diagnosis of malignant disease in the mesopharynx, the tonsil being the commonest structure involved. Its diagnosis having been made, x-ray or radium is the present accepted method of therapy in preference to any attempt at surgical excision.

TREATMENT OF LESIONS OF THE HYPOPHARYNX

Infections.—Acute Laryngitis: The primary and most efficacious form of treatment of simple acute laryngitis is absolute and complete vocal rest. Patients, if possible, should not be permitted even to whisper for at least three to five days. The frequently associated tracheitis is best controlled with an appropriate cough medicine containing such hypnotics as codeine or morphine, by inhalation of steam medicated by compound tincture of benzoin and particularly by the intratracheal instillation of soothing, oily medications such as pinoleum or the more complex monochlorophenol. Such medications can, under guidance of the laryngeal mirror, with fre-

quently necessary preliminary cocaineization, be instilled with a laryngeal syringe directly onto and between the vocal cords during deep inspiration. I believe that this local treatment, carried out daily for two or three days, can be supplemented by the use at home of an infra-red lamp and also by applications applied about the neck of cotton sheet wadding saturated with isotonic salt solution. With evident improvement in the appearance of the vocal cords, the patient may be permitted to whisper for the ensuing week and then gradually resume the use of his voice, being careful, however, for some time to avoid any extra demand or strain on it. Whenever, particularly in children, the element of obstruction is added to the less serious symptom of hoarseness, the picture at once becomes more complicated and the physician must apply therapeutic measures often much more drastic in nature. Of chief importance is the recognition of such obstruction before it becomes so serious as to constitute an emergency. Simple spasmodic croup will yield to the placement of the patient in a warm moist atmosphere, to the use of expectorants, and particularly to reassurance of both the patient and the parents. Diphtheria would of course be suspected in the presence of any diphtheritic membrane elsewhere in the throat, but absence of the latter does not rule out laryngeal diphtheria and with any evidence to suspect contagion antitoxin would wisely be administered.

Persistence of obstruction, however, must always give rise to the suspicion of some more serious underlying cause such as the disease now commonly known as laryngotracheobronchitis. Any suspicion of the existence of this disease or even a simulating condition, such for instance as foreign body in the larynx or true streptococcic laryngitis, would warrant immediate transfer of the patient to a hospital, where direct laryngoscopic examination could at once be carried out. On the observations attending this procedure depends the application of appropriate therapy. In the presence of diphtheria, membranes can be removed by suction or by forceps and an intubation tube placed within the larynx.

An obvious foreign body can be removed in the manner best adapted to its nature and, in the case of laryngotracheobronchitis, a decision can be made after direct examination of the larynx as to the desirability of tracheotomy. In spite of the immediate relief afforded by it, intubation as a general rule is not satisfactory in laryngotracheobronchitis and its employment will only lead to further difficulty later on. The value of sulfanilamide or sulfapyridine has not yet been clearly established in these more severe forms of laryngeal infection. My own experience with sulfapyridine has seemed to indicate its value as a therapeutic adjunct but only in conjunction with complete relief of the laryngeal obstruction and never to be relied on in the presence of severe dyspnea. Of the utmost importance in the care of such patients following tracheotomy is the humidification of the patient's room by some form of mechanical humidifier capable of instituting, in as small a room as possible, a wet and dry bulb thermometer humidity of as near 100 per cent as possible. By this means one may be most nearly assured of preventing the dreaded crust formation in the lower portions of the respiratory tract which has proved such a serious factor in the care of patients afflicted with laryngotracheobronchitis.

Chronic Laryngitis: Chronic laryngitis, incident usually to long-standing abuse of the voice, is to be

treated on somewhat the same line as acute laryngitis but over a longer period of time and with some regard for the necessity of the patient's carrying on to some extent his normal activity. He should, if possible, be put on a whispering regimen for anywhere from one to three months. Local instillations into the larynx of soothing medications by means of the laryngeal syringe have already been described. Avoidance of laryngeal irritation incident to smoking, to the use of alcohol and to dusty and irritating atmospheres is important. If the original disability is the result of improper use of the voice, particularly in speakers and singers, educational factors must enter the picture and the patient, if possible, taught proper use of his voice. Underlying and predisposing causes which may arise in other parts of the body system must be given attention, particularly the nose and nasal sinuses, as being a primary cause of secondary chronic laryngeal irritation. Obviously no patient can safely be assumed to have simple chronic laryngitis unless other simulating conditions in the larynx have been ruled out by careful and reliable laryngoscopic examination. Where such examination shows the presence of pus and accumulated dry secretions, consideration must be given to the similarity of this condition with that of atrophic pharyngitis and rhinitis and to the utilization by swabbing in the larynx of one of the various estrogenic substances which have proved so effective in other parts of the respiratory tract.

Laryngeal Tuberculosis: This disease represents an instance of the importance of accurate laryngologic examination with the laryngeal mirror as being the only means by which differentiation can be made in many chronic laryngeal lesions producing hoarseness as almost the only symptom. There is no typical laryngeal picture for tuberculosis and only experience will lead gradually to ability to make a correct estimate of the laryngeal picture. An antituberculosis regimen is obviously essential, since in almost every instance of laryngeal tuberculosis the patient will be found to be suffering also from pulmonary tuberculosis. Locally my preference is for puncture cauterization of the tuberculous lesions in the larynx performed by means of direct laryngoscopy. Marked dysphagia may be relieved by injection or section of the superior laryngeal nerve.

The same importance of accurate diagnosis also obtains in the case of hoarseness due to syphilitic lesions of the larynx. The clinical appearances may be still more bizarre even than those of tuberculosis and there is no diagnostic pattern on which one can definitely rely. Serologic tests will of course lend credence to this diagnosis, the treatment being that of syphilis of other parts of the body.

Tumors of the Hypopharynx.—The treatment of tumors, either benign or malignant, in the hypopharynx, particularly in the larynx, depends to a considerable extent on the nature of the new growth. Many times simple surgical excision will suffice whereas in other instances, particularly in advanced malignant disease, the most radical forms of surgery or intensive irradiation may be appropriate. Such work is now falling more and more into the hands of those who take a special interest in this subject and who by extensive experience have developed a special skill for such work. For the average laryngologist it is of especial importance that by early and frequent indirect laryngoscopic examination he be alert to detect the presence of any incipient new growth before it advances to the stage requiring

radical treatment. This is of particular importance in the case of cancer of the larynx, in which early diagnosis is so important from the standpoint of the patient's future well-being. Suspicion of a new growth in the larynx will frequently warrant substantiation by biopsy carried out by means of direct laryngoscopy, on the results of which will depend the character of subsequent surgical treatment.

Foreign Bodies in the Hypopharynx.—Foreign bodies in the pharyngeal end of the esophagus are usually not visible on direct inspection. Much will depend on the history given by the patient, since this will often reveal the nature of the foreign body. From a therapeutic standpoint removal is, of course, indicated, usually by the direct esophagoscopy method. The same is true of foreign bodies in the larynx, but, since these so frequently occur in children and since there is often no direct history of aspiration, the true nature of the obstruction may not at once be evident and for this reason inappropriate therapy, such as the administration of diphtheria antitoxin, may erroneously be applied. The importance of relief of such laryngeal obstruction pending removal of the foreign body has already been stressed in connection with inflammatory laryngeal obstruction.

Throat inflammations complicating systemic disease must frequently come under observation, particularly of the general practitioner. Prominent among these is the sore throat incidental to scarlet fever and that seen in mononucleosis and agranulocytic angina. The blood picture is most important in diagnosis and the treatment is that of the underlying condition.

Laryngeal Paralysis. The treatment of hoarseness due to various forms of laryngeal paralysis depends entirely on the etiologic factor. Trauma to the recurrent laryngeal nerve or compression of this nerve by pathologic conditions within the thorax must be treated entirely from the etiologic standpoint. Where such paralysis entail severe obstruction to breathing, tracheotomy may be the only feasible method of at least temporary relief.

Central nervous system disease producing such paralysis often entails many diagnostic difficulties before intelligent treatment can be applied. Weakness of the approximating laryngeal muscles and certain forms of hysteria producing weakness or fatigue of the voice must frequently be treated from a psychologic standpoint and by instruction in proper use of the voice. Almost all therapy is dependent first of all on careful and intelligent mirror examination of the larynx.

319 Longwood Avenue.

Heat Stroke and Heat Prostration.—Occasionally in periods of extreme heat and humidity great numbers of people may be prostrated, as though the affection were epidemic. The mildest effect (heat prostration) consists in headache, moderate rise in temperature, pains in back and limbs, and extreme exhaustion. More severe is the asphyctic form, in which great dyspnea and cyanosis, with delirium or unconsciousness, are added to these symptoms. Still more severe, and very frequently fatal, is the hyperpyretic type, in which unconsciousness and collapse come on suddenly, or after several days of vague premonitory symptoms. There are convulsions, delirium, or profound coma, with shallow and grasping or very deep respiration, and finally failure and stoppage of the heart. The skin, at first covered with sweat, becomes hot and dry, and the temperature rises to phenomenal levels.—MacCallum, W. G.: *A Textbook of Pathology*, Philadelphia, W. B. Saunders Company, 1940.

TREATMENT OF ACUTE AND CHRONIC SUPPURATIVE OTITIS MEDIA

HAROLD I. LILLIE, M.D.

ROCHESTER, MINN.

Not so long ago some one asked "What is wrong with present day methods of treating otitis media?" The question startled me. Complacent in the thought that patients seemed to be doing well under the management being used, I wondered if the question really meant "Why can we not control the complications of otitis media?" It must immediately be realized that, once an infection has occurred within the middle ear, it can be assumed that the infection has extended to the appendages, because of the very nature of the anatomic arrangement of the structures. The only portion of the tract that can be treated directly is the middle ear. Assuming that the diagnosis of acute otitis is made correctly, what should be done?

First of all, the serious nature of the disease must not be minimized. The patient should be hospitalized and confined to bed in a nearly upright position. The room should be warm and moist. Appropriate treatment of any respiratory infection should be instituted and it must be insisted on that the patient not blow the nose. Hot moist dressings applied over the ear and mastoid are effective in ameliorating symptoms. Roentgenologic treatment of the ear in the early stages of the condition has been found to afford considerable relief of pain for many patients.

There seems to be no unanimity of opinion regarding the indications for and usage of myringotomy in suppurative otitis media. Some observers say they perform myringotomy on all patients at the first sign of involvement in the middle ear. Others use myringotomy when severe pain is complained of, even though no bulging of the drum is present. Others prefer to await the presence of classic signs such as (1) fever, (2) severe pain, (3) redness and (4) bulging. That the composite condition must be individualized and appropriate treatment used is the consensus. If the first signs in the ear are those referable to tubotympanitis, institution of palliative measures certainly seems logical, whereas, if all signs are present, myringotomy is indicated. If the surgeon is undecided, he may use myringotomy without reflection on his diagnostic ability or judgment. If myringotomy is deferred, any of the standard medicaments may be used in the ear. In addition to the effect it has on the pain, the use of a medicament helps partially to sterilize the canal. During this period other necessary examinations may be carried out. If myringotomy is decided on as a primary method of treatment, the operation is best performed under general anesthesia. An adequate incision of the tympanic membrane, and not merely a puncture wound, should be insisted on. The posterior quadrant of the tympanic membrane is the most suitable site for myringotomy. It is too much to expect that myringotomy will prevent surgical mastoiditis in every instance, and relatives of the patient should be so informed. Myringotomy may help, but the underlying pathologic processes may not be confined to the middle ear and conditions may not be suitable for drainage of the adjacent infected structures. Myringotomy may be expected to relieve the intense pain

From the Section on Otolaryngology and Rhinology, the Mayo Clinic. Read before the Section on Laryngology, Otolaryngology and Rhinology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

caused by the effects of pressure of fluid confined in the middle ear; also it may be noticed in children that elevated temperatures may subside after performance of myringotomy. It is important that cultures of the discharge from the middle ear be taken and the infecting organism be identified, because this knowledge may be of great importance in the management of the disease. However, the importance of the organism found may easily be overemphasized.

It is my opinion that it is best not to resort to irrigations of the auditory canal if the discharge from the ear is free. Irrigation of the auditory canal should not be done until the discharge becomes thick and purulent. Hot moist compresses should be kept applied over the ear and the mastoid process because their use seems to encourage free discharge.

Careful observation of body temperature, pulse and respiration and the use of laboratory tests are essential because the progress of the patient may best be followed if these observations are correlated. I have always felt that the general appearance and demeanor of the patient are good indexes of the general condition. Blood tests are particularly important, especially the estimation of the hemoglobin percentage and culture of the blood. Tests made daily are not necessary. Small children are unduly antagonized and made more difficult to manage and are less cooperative if tests are made daily.

The use of sulfanilamide is rather general at present, and the literature is filled with strikingly successful instances of its use. On the other hand, it is equally true that warnings are being sounded by very competent observers to the effect that the use of the drug may seriously mask the signs and symptoms of actual underlying pathologic processes. Patients receiving this drug must be hospitalized to insure adequate observation. Recognition of a new clinical picture may need to be learned if the use of sulfanilamide is insisted on. It seems to have been well established that the drug and its derivatives have little beneficial effect in actual infections of the bone but that they are effective against infections involving the soft tissues. If infection of the blood stream or extension of the infection into the intracranial structures is present, the original infection in the ear and mastoid cells must be eliminated and sulfanilamide or its derivatives should be used as an adjunct therapeutic agent.

It must be decided on which type of mastoiditis is present. If osteothrombotic mastoiditis is present, the discharge from the ear will be thin and the roentgenogram usually will show a small cell variety of mastoid process with little or no changes suggestive of destruction. Earlier evidence of complications as manifested by high fever, nephritis and a decreasing percentage of the hemoglobin may be expected. Evidence of invasion of the blood stream may occur in this type of disease even after the discharge from the ear has ceased.

If the pathologic process is suppurative, the discharge from the ear will be purulent and the roentgenogram will show evidence of destruction of the cellular structures. The blood count more generally shows an increase in the number of leukocytes, and the decrease in the percentage of the hemoglobin is not so striking. Complications, because of the very nature of the disease, occur later in the course.

When has resolution taken place? Many factors must be considered. The general appearance and demeanor of the patient are good indexes. If the patient continues to look and act as if he were ill, even though the ear appears to be doing well, the physician should be sus-

picious of impending complications. If the patient looks and acts as if he were normal, even though the ear is still discharging, it is rather good evidence that no complication is impending. There is no set period for final resolution to be established. Every patient seems to constitute a law unto himself. Also there is not a set time at which surgical intervention is indicated; it depends entirely on the nature of the pathologic process and the good judgment of the surgeon. The patient should be observed throughout the course of the disease if chronic suppurative otitis is to be avoided.

Too often for accurate comprehension, chronic otitis media is dealt with in the abstract. To speak in generalities about a disease of such variable clinical characteristics as chronic otitis media is too confusing. Dividing chronic otitis media, for purposes of discussion, into nondangerous and dangerous groups is not sufficient for clearness of immediate perception of the actual pathologic process under discussion. Because clinicians must correlate all the facts in a given case to arrive at some worth-while conclusion, it is important to realize that clinical problems cannot be reduced to the status of mathematical precision. To rely on statistics is a dangerous philosophy in the everyday practice of medicine. One famous aural surgeon said that all ears in which a chronic condition is present should be operated on. That rather obviously is a philosophy which cannot be subscribed to by experienced observers; it is as wrong as it would be to say that there is no need to operate in any case of chronic otitis media. Recently I heard an otologist say that he had never failed to cure what he called a "chronic ear" with a certain combination of drugs in solution. When he was asked what types of "chronic ear" he meant, he said that all types had responded to the treatment. It is such statements as this one that make for confusion.

In general, it can be said that the treatment of chronic suppurative otitis media should be carried out by an otologist. The frequency of treatment is entirely dependent on the nature of the disease. Treatment must be persistent, well directed and meticulous. To wash out the discharge with aqueous solutions is not good treatment because the effect of water is to soften epithelium and cause increased desquamation in addition to producing a very suitable condition for the growth of bacteria. For these reasons the use of alcoholic solutions is preferable. Manipulation with instruments may be necessary to remove collections of desquamated material, aural polyps causing obstruction to underlying cavities or recesses, and to remove exuberant granulation tissue. At the first visit of the patient it may not be possible for the otologist to do all he would like to do because the patient may be too apprehensive. As confidence is gained, more can be accomplished. From an economic standpoint, persistence in local treatment may be favorable from the patient's point of view. If the treatment is not entirely successful and if surgical intervention is decided on, it will be found that the local treatment has prepared the field well and that the period of postoperative treatment will be much less prolonged for that reason. Treatment at home under the direction of the otologist is not effective until the pathologic process has been brought well under control.

FOUR CLINICAL TYPES OF CHRONIC SUPPURATIVE OTITIS

Patients affected with chronic suppurative otitis media may be divided clinically into four groups. For purposes of discussion the following grouping will afford

a rather clearly defined mental picture of a given case so that any otologist should know at once what pathologic condition actually is being discussed. The clinical management of patients in each group is based on the recognition of the underlying pathologic process. Time does not permit a comprehensive exposition of all the factors involved.

GROUP 1.—Patients comprising this group include those in whom antero-inferior perforations of the tympanic membrane overlie the orifice of the eustachian tube. Few subjective symptoms are complained of other than discharge from the ear. The discharge usually is increased in the presence of head colds. The discharge is mucopurulent in character and is without odor unless care of the ear has been neglected and unless the detritus has undergone saprophytic infection. The treatment is directed at the nasopharynx, eustachian tube and middle ear. The patient's blowing of his nose should be stopped, or else he should be instructed in the proper physiologic method of blowing the nose.

GROUP 2.—Included in this group are those patients who may have had considerable central loss of the tympanic membrane and show evidence of definite pathologic change in the membrane covering the promontory. Hyperplasia and granulation tissue are frequently encountered. In addition, the malleus may be involved by a necrotic process. However, there is little evidence of pathologic changes in the attic. When the infection is controlled, the promontory becomes covered with epithelium if the periosteum has not been too seriously damaged by disease. Patients who have this condition respond well to local treatment. Alcoholic solutions to which certain antiseptic agents are added and antiseptic powders are the usual agents employed. Drying with a stream of air is used. Zinc ionization is said to be useful in this particular type of condition.

GROUP 3.—No destruction in the tympanic membrane may be evident in this group of patients but defects into the attic of various sizes and situation are seen. However, partial or total destruction of the tympanic membrane may be present in addition to the lesion in the attic. In many instances the tense portion of the tympanic membrane may be intact. Since the perforation present is of the marginal type, formation of cholesteatoma can be expected. In addition, the occurrence of necrosis of bone is not unusual. From the defect in the attic, foul smelling pus may be discharged and visible evidence of cholesteatoma is likely to be present. Subjective symptoms, in addition to the malodorous discharge, such as pain or headache and mild attacks of vertigo, may be complained of by the patient. The hearing may be but slightly affected. The condition of patients in this group can be considered to be "borderline surgical." The effect of treatment will depend on the size of the defect into the attic and mastoid region. If the defect is large enough to permit instrumentation and direct treatment, the result may be very satisfactory and, if there are no symptoms of impending complication, treatment may be persisted in. A surprising number of patients in this group have remained well. If surgical intervention becomes necessary, the modified radical mastoid operation can be employed satisfactorily in those cases in which the tympanic membrane has not been destroyed by the disease. It is in this group that natural reparative processes may fashion a cavity similar to that for which the surgeon would hope if he had performed an adequate operation.

GROUP 4.—In addition to the pathologic processes discussed in group 3, those patients whose condition classifies them in group 4, present definite evidence of serious pathologic changes with or without symptoms or impending serious complication. The condition of such patients is surgical and demands adequate surgical intervention at the earliest convenience because there is little likelihood that treatment will affect favorably the condition and, what is more important, delay in instituting surgical intervention is fraught with great danger to the life of the patient.

THE TREATMENT OF ACUTE AND CHRONIC SINUSITIS

J. MACKENZIE BROWN, M.D.

LOS ANGELES

The treatment of sinusitis cannot be prescribed in hard and fast rules. Individualism in therapy is as essential here as in any other branch of medicine. The following general rules are given but may be adjusted to the individual needs of the patient:

THE GENERAL TREATMENT OF ACUTE PANSINUSITIS

In acute pansinusitis the patient should be kept in bed in a room with a warm even temperature day and night. Nasal shrinkage should be accomplished with either ephedrine or neosynephrine in warm physiologic solution of sodium chloride. The spray should be repeated in from ten to fifteen minutes in order to reach the superior nasal regions. In fulminating cases with threatening orbital complications, cocaine or epinephrine may have to be used. Even though the secondary reaction from the use of these drugs may be marked, the added shrinkage obtained may cause the offending sinus to evacuate itself and prevent complications.

In small children it is preferable to use the dropper method. The child is placed in the recumbent position, the head fully extended over the edge of the bed, and about three drops of the solution put into the nose. This should be repeated in from ten to fifteen minutes.

Relief of pain in the acute stage is obtained by the use of drugs and physical measures. Acetylsalicylic acid and codeine should be given as often as necessary. Heat or cold may be used in the form of local applications, according to individual preference. Heat may be utilized in any one of many ways. I am convinced, however, that it is the heat alone that gives relief, and not the method through which it is used.

In severe infections, chemotherapy and immunotherapy may be indicated. In beta-streptococcal sinusitis, sulfanilamide is advised. In pneumococcal sinusitis, sulfapyridine, and in staphylococcal sinusitis, the newer derivative sulfathiazole has been of value experimentally. In cases of streptococcal sinusitis in which sulfanilamide is not well tolerated or ineffective, convalescent scarlet fever serum may be used with great benefit.

In the subacute phase of pansinusitis, when the patient is afebrile and usually free from pain, after thorough nasal shrinkage the nose is gently irrigated with warm Ringer's solution to remove accumulated mucus, or a displacement treatment (Proetz) is done. I have found these to be important measures in ridding the patient of the infection. In this stage a warm climate

From the Department of Otolaryngology, the University of Southern California School of Medicine.
Read before the Section on Laryngology, Otolaryngology and Rhinology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

is of great value. It is important, however, that these patients keep their rooms warm at night, since the temperature may frequently drop from a high level in the day to a low one at night.

ACUTE MAXILLARY SINUSITIS

In the acute stage of maxillary sinusitis, irrigation of the antrum is contraindicated. The lining membrane of the antrum is hyperemic and markedly edematous; therefore no benefit is accomplished by irrigation, and harm may result.

In the subacute stage, when exudation is the prominent pathologic process, the antrum usually contains a considerable quantity of thick pus. If the retention of this pus produces persistent pain and discomfort, in spite of shrinkage, irrigation of the antrum is indicated. The antrum may be irrigated through either the inferior or the middle meatus. The choice of route will depend on the practice and preference of the individual surgeon as well as on the anatomy of the nose. Such an irrigation will remove a large amount of thick pus, which would find exit only with great difficulty or not at all through the natural opening, if untreated.

ACUTE MAXILLARY SINUSITIS DUE TO DENTAL PATHOLOGIC CONDITIONS

Cases of acute maxillary sinusitis due to dental pathologic conditions are definitely not secondary to any nasal infection and are confined to the antrum alone.

Without Extraction.—Acute maxillary sinusitis due to dental infection not following extraction is uncommon. The very earliest stage is a short inflammatory phase. The next stage, that of exudation, is the one commonly seen when symptoms first appear. As soon as the diagnosis is established, the antrum should be irrigated. At a later date, when the acute process has subsided, the offending dental pathologic condition should be removed. After this the irrigations should be continued until the infection subsides.

Following Dental Extraction.—If an opening exists between the antrum and the tooth socket, the antrum is irrigated through this opening as soon as the sinusitis is recognized. If no opening exists between the tooth socket and the antrum, irrigation should be done through the nose.

ACUTE ETHMOIDITIS

Acute ethmoiditis is most frequently associated with infection of the other sinuses and will usually respond to the general treatment outlined. If orbital extension occurs, three types may be observed: first, simple edema of the orbit; second, periorbital abscess, and third, the less common, true orbital abscess.

Simple orbital edema will usually respond to intensive nasal shrinkage. If orbital induration with fixation of the eyeball is present, it is an indication for surgical intervention. An external approach is advised and should endeavor only to allow adequate drainage but should not include a complete exenteration of the ethmoid cells. If the latter procedure is necessary, it should be done at a later date, after the subsidence of the acute process.

ACUTE SPHENOIDITIS

During the acute stage of sphenoiditis only general treatment should be carried out.

In the subacute stage, after recession of nasal congestion, the sphenoid sinus may be irrigated through the ostium. In children the persistence of an unexplained fever following an acute sinusitis should suggest the possibility of a sphenoiditis.

ACUTE FRONTAL SINUSITIS

Acute frontal sinusitis should be treated first by intensive shrinkage. If ephedrine or neosynephrine does not suffice, epinephrine and cocaine should be used. They may be employed in the form of pledgets placed in the middle meatus. Even though epinephrine has a very marked reaction from one to two hours after its use, the immediate shrinkage obtained may be sufficient to initiate drainage of the sinus.

Early external drainage of the frontal sinus should be considered if, in spite of intensive shrinkage, persistent pain and tenderness with or without swelling of the upper lid or supra-orbital region is present. If the sinusitis is the result of swimming, external drainage should be considered earlier than otherwise. The external drainage should be confined to a simple trephine in the inner third of the floor of the sinus.

It is imperative that an x-ray examination of the frontal sinus should be made in order to determine the presence and dimensions of the sinus before surgery. With the external opening a more adequate drainage is obtained without the dangers of traumatizing the acutely inflamed nasal mucosa. If meningeal signs become apparent, the posterior plate should be removed at once, or if signs of osteomyelitis make their appearance, in spite of adequate external drainage, more extensive surgical procedures on the frontal bone should be employed without delay.

PRINCIPLES OF TREATMENT OF CHRONIC SINUSITIS

In chronic sinusitis a general physical examination of the patient is of the utmost importance as well as the routine special examinations, including adequate radiography. Factors of importance include endocrine dyscrasia, excessive use of tobacco and alcohol, and vitamin and other dietary deficiencies.

It should be kept in mind that certain cases of chronic sinusitis are basically of an allergic nature with superimposed pyogenic infection. Unnecessary surgery may be avoided by investigation of this angle.

If septal deflections are present which may obstruct sinus drainage, these should be corrected. Infected tonsils and adenoids should be removed, in order to prevent upper respiratory infections and recurrent sinusitis. In children it is not uncommon for an acute exacerbation of a chronic sinusitis to follow tonsillectomy. The removal of tonsils and adenoids in children is frequently all that is necessary to clear the sinus infection.

CHRONIC MAXILLARY SINUSITIS

In chronic maxillary sinusitis, displacement treatments may be tried but irrigation of the antrum is suggested. If the infection persists after a reasonable trial with irrigations, an antrum window is indicated. In making the antrum window I would suggest that the opening be made far forward and low on the floor and not too far back, and that it be done with biting forceps or sharp instruments in order that the edges of the opening may not be unduly traumatized. There is less probability of excessive granulation if biting forceps are used instead of rasps. If the opening is made too far back, there is danger of hemorrhage from a branch of the sphenopalatine artery. If the opening is made too far back and high up, the attachment of the inferior turbinate is weakened with a subsequent in-drawing of the turbinate. The formation of adhesions follows with the ultimate closure of the window.

Complications associated with suppurative mastoiditis when pneumatization is extensive which results in bone perforation with the extension of infection into neighboring soft tissues are as a rule observed to better advantage on clinical inspection than by means of roentgen examination. Such perforations are to be looked for in the zygomatic region, in the area immediately posterior to the ear and in the form of Bezold's abscess. Occasionally cortical destruction of the mastoid can be identified radiographically, although ordinarily necrosis of cell walls in the immediate vicinity rather than the actual perforation itself is all that one can find. Perisinal abscess, when sufficiently extensive, may be detected on the basis of neighboring bone destruction along the course of the sigmoid sinus.

The serious complication of petrositis has attracted a good deal of attention by otologists and roentgenologists in recent years. Many articles devoted to the discussion of normal relationships and observed developmental variations of the petrous portion of the temporal bone, as well as roentgen evidences of disease, have appeared in the literature. Roentgen examination is usually requested for the purpose of confirming suspicions based on clinical signs with the hope that perhaps some idea of the extent of the process may be gained.

By general usage, petrositis has come to mean inflammatory disease involving that part of the petrous bone which lies medial and anterior to the arcuate eminence and the superior semicircular canal. This portion of the temporal bone consists of cancellous or spongy bone containing marrow and a variable number of air containing cells. The spongy portion of the bone is encased by a dense cortical layer. The occurrence of air cells within the petrous bone has been variously quoted at from 11 to 35 per cent of all observed cases. Fowler and Swenson³ were able to identify at least a few cells in the petrous bones of all of 369 adult patients whom they studied. In only twelve of these would they report extensive pneumatization. In poorly pneumatized bones some cells were found in the peritubal area, above the jugular bulb and in the epitympanum. Cellularity of the petrous process is usually proportionate to the number of cells found in the mastoid process. Roentgen signs of suppurative disease involving cells within the petrous portion of the temporal bone do not vary from those which are useful in estimating the status of the mastoid process, although signs of clouding and cell wall destruction are as a rule recognized with greater difficulty. The belief is generally accepted that dissemination of mastoid disease in the petrous bone is directly dependent on cellularity in this area. Once extension has occurred, however, true osteomyelitis may develop in the marrow-containing portion of the petrous pyramid. Under these circumstances bone destruction may extend well beyond the site of recognizable cells if the infection is severe. In more indolent infections, sclerosis may develop far into the body of the petrous bone. Roentgen signs of petrositis can be considered of value only when they confirm clinical manifestations of such disease or when they are helpful in determining the most desirable method of surgical treatment.

Brain abscess complicating suppurative mastoiditis may exist in the absence of telltale roentgen signs. Occasionally displacement of calcification within the choroid plexus and pineal body has proved helpful in

detecting the presence of intracranial mass to one or the other side of the midline. At least one instance of a brain abscess containing gas produced by the infecting organism and directly associated with mastoid disease has been reported. In this case the presence of the air bubble resulted in localization following x-ray examination. Once localized, the surgical treatment of brain abscess can be facilitated by the injection of opaque contrast mediums directly into the cavity by way of an exploring needle. After such injection roentgen examination offers valuable information regarding the size and exact location of the abscess. Kahn⁴ has reported the progressive extrusion of abscesses so injected toward a well placed decompression defect in the skull.

The complication of cranial osteomyelitis is only rarely associated with mastoid disease. In the few instances which have been encountered at the University Hospital the situation was not recognized in preoperative roentgenograms. In one case, however, unequivocal signs of osteomyelitis were demonstrable, progressing beyond the margins of the operative defect following operation.

Primary tumors of this region are extremely rare. Carcinoma associated with chronic middle ear disease has been described. The roentgen signs of this lesion with extension to the mastoid are not characteristic. The degree of bone destruction may be more marked and localized than is to be expected from suppurative disease. At our hospital in recent months extensive cranial destruction in the region of the temporal bone of a young child was found at operation to represent a large lymphosarcoma. It is well to remember that Schüller-Christian's disease may produce extensive mastoid destruction in infants. In this disease multiple lesions throughout the skull and elsewhere in the skeleton may be depended on to reveal the true nature of the situation.

CONCLUSIONS

Complications of suppurative mastoiditis other than those here discussed may from time to time be encountered. One may expect with confidence to recognize such extenuating circumstances when they do occur only if routine roentgen examination is conducted with great care and precision. In this particular field of roentgen diagnosis, accurate technic and sound dispassionate judgment are of paramount importance if unusual circumstances are to be recognized and evaluated.

University Hospital.

ABSTRACT OF DISCUSSION

DR. ISIDORE FRIESNER, New York: Dr. Johnson's paper represents the present evidence of accord between the roentgenologist and the clinician as to the method of roentgenology and the value of roentgenograms in the diagnosis of disease in the temporal bone.

DR. FREDERICK M. LAW, New York: I have to speak from the standpoint of a roentgenologist. I agree with everything which has been said. I have two observations which I should like to make. Sulfanilamide is a valuable drug but a treacherous friend. When it is administered, the case must be followed by a series of x-ray films in order to obtain a knowledge of what is taking place within the mastoid process. When given early, before any involvement of the bone occurs, the prognosis is good; but if administered after beginning bone change, the symptoms are relieved, the patient feels fine, but the drug has no effect on the bone other than a delayed action of the process.

3. Fowler, E. P., Jr., and Swenson, P. C.: Petrositis: A Roentgenological and Pathological Correlation, *Am. J. Roentgenol.* 41: 317-342 (March) 1939.

4. Kahn, E. A.: The Treatment of Encapsulated Brain Abscess with Visualization by Colloidal Thorium Dioxide, *Univ. Hosp. Bull., Ann Arbor* 4: 17-19, 1938.

When the drug is discontinued the bone destruction proceeds, just as though no drug has been administered, and it is absolutely necessary to use follow-up films, which should be stereoscopic, as stressed by Dr. Johnson. I have had reports that operation following the administration of sulfanilamide showed complete destruction of the bony walls, whereas the x-ray examination showed cell structure present. The reason for that is, films were not made stereoscopically to obtain the third dimension, and the apparent cell structure shown on a single film is caused by a layer of complete and incomplete cells immediately under the cortex. Visualization in the third dimension would have shown that the deeper cells were destroyed. I feel that one must have absolute faith in the films in order to know the progress of the case. We know that resolution occurs in the presence of bone necrosis, but it is safer to be aware of the condition than to feel comfortable in the absence of all symptoms. The other condition I should like to speak of is petrositis. Marked involvement of the petrous bone can be shown on a roentgenogram but I should like to add a word of caution against interpretation with only a single set of films. One should be made at the beginning of mastoiditis in order to have a comparison for future trouble. The petrous bone is just as susceptible to anatomic variations as any other bone of the skull, and I have seen variations in the structure simulating petrositis with absorption of the petrous bone. Films taken for a regular sinus involvement will many times show an anatomic variation which must be considered in analyzing the appearance in the presence of positive symptoms.

VULVAR FUSION

ITS UROGYNECOLOGIC INTEREST

MEREDITH F. CAMPBELL, M.D.

Professor of Urology, New York University College of Medicine
NEW YORK

Fused vulva (synechia vulvae) designates the condition characterized by an embryonal midline sealing together of the labia minora; usually a minute unfused area is left well forward, and through this orifice the child urinates. The foregoing represents the incomplete variety of fusion which in statistical studies occurs in approximately a third of the cases; in complete fusion the vulvar union is total. Although I could find nothing in American medical literature of the past twenty-five years appertaining to this subject, surely this does not represent the true incidence of the condition. Yet the appearance of the anomaly is so striking that its correct recognition could scarcely fail to provoke at least a few case reports. Curiously, in none of the nine cases of this condition which I have seen during recent years was the anomaly recognized until some time after birth. All the cases that I have seen were thought by their original observers to be instances of hermaphroditism or pseudohermaphroditism. All the patients except one (8 years) were less than 2 years old; the youngest was 4 months.

ETIOLOGY

This condition may be either congenital or acquired. In the acquired type, it has been thought by some that intra-uterine inflammation causes a sealing together of the labia minora or of the vaginal orifice. Other hypotheses include post partum vaginal inflammation; the sealing together results from cohesion of the inflamed tissues.¹ The explanation which seems most rational is that of an embryologic midline fusion of the labioscrotal folds on each side similar to that which the two scrotal folds undergo in the male, but the fusion usually lacks

the density of scrotal fusion. This scrotal union occurs between the third and fourth months of fetal life. Although I have not found this theory recorded in the literature of the subject, I question that it is original with me.

Acquired vulvar fusion is said to follow local inflammation consequent to acute infectious diseases such as cholera, smallpox, diphtheria, scarlet fever, pneumonia, typhoid and typhus.² Yet I can find no description of an authentic case of this variety. In view of this, one may consider the condition predominantly a congenital anomaly.

REPORT OF CASE

The following case history of the first and oldest child in this series suggests the usual clinical problems these patients present. Diagnostic error and therapeutic delay may entail both preventable suffering of the child and much needless anxiety of the parents.

T. S., a girl aged 8 years, was admitted to the Children's Medical Division of Bellevue Hospital July 21, 1930, because of recurrent attacks of "pyelitis" for the past nine months. With these attacks there had been low grade fever and backache. Examination of the voided urine specimens repeatedly showed many pus cells, and on this observation the diagnosis of pyelitis rested. Labial examination on admission to the hospital (an attempt to obtain a catheterized urine specimen had been made) revealed an unusual labial formation. A gynecologic consultation was requested and the examination was made by an excellent gynecologist who noted that the abdomen was normal. The vagina, labia minora and majora, clitoris and a supposed urethral opening were present. The vaginal introitus was completely occluded by thick fibrous tissue. Rectal examination did not disclose the presence of any uterine body or adnexa; the patient was partially resistant to examination. A diagnosis was made of congenital malformation of the generative tract with absence of vagina, uterus and adnexa. It was suggested that the mother be advised of the condition and that the patient return for reexamination at about the age of puberty.

One week later the child was referred to the department of urology for cystoscopic observation, but this was not accomplished because of my inability to locate the external urethral meatus through the minute opening in the fused labia minora. Three days later, with a finger in the rectum as a guide, a probe was introduced 2 inches upward into the cervical area. The appearance of the fused labia will be described later. I noted at the time that the vagina and uterus were present and that it seemed that the vaginal canal would be exposed by incisional separation of the "perineal" mucosa in the midline. The following day (August 8) the patient was seen by an eminent gynecologist, who noted the opinion that the patient probably had a congenital anomaly, perhaps the absence of generative organs, and that as she defecated and urinated normally there was no indication for operative intervention until the age of puberty. The latter note dismissed the child from gynecologic consideration for one year. One month after the note was made an excretory urographic series (with neo-iopax) disclosed a morphologically normal urinary tract.

One year later (Sept. 15, 1931) the child was returned to me, at which time I took it on myself to correct the anomaly. The fusion of the labia minora was gently broken down without discomfort, revealing a normal hymen, vagina and urethra. Vaginal endoscopy disclosed a normal appearing cervix. Petrolatum dressing and special cleanliness were employed for one week. In June 1933 the urine was normal, including bacteriologic culture. There were no complaints. At the age of 16 years (1937) the child still had no complaints and was developing normally in every respect.

PATHOLOGIC AND CLINICAL CONSIDERATIONS

The appearance of the fused labia minora is striking and is likely to be extremely confusing to one who never before has seen it. The interlabial (majora)

ulcerative colitis in three Frei positive patients and attributed the colitis to lymphogranuloma venereum. Paulson¹¹ prepared antigens from the colonic exudates of patients with chronic ulcerative colitis with and without positive Frei reactions and obtained positive cutaneous tests in cases of lymphogranuloma venereum and negative tests with healthy persons or patients suffering from other conditions. Dick⁸ and Goodman,⁹ however, failed to obtain satisfactory Frei antigen from the pus aspirated from the perirectal abscesses in a case of inflammatory rectal stricture with a positive Frei test or from ulcerated areas of the colon at autopsy in a case of chronic ulcerative colitis with a positive Frei reaction.

Since a large number of patients with nonspecific ulcerative colitis were available, we decided to pursue the study of this question. All such patients were studied with regard to the Frei reaction and the neutralizing powers of their serums against the virus of lymphogranuloma venereum. Attempts also were made to isolate the virus from the tissues of selected cases.

FREI TESTS

In the performance of the Frei test we used a mouse brain antigen prepared according to the usual technic from a strain of the virus of lymphogranuloma venereum isolated by us from pus aspirated from the enlarged inguinal node of a patient in the third week of the infection. This strain has gone through forty-six consecutive mouse passages to date and has yielded consistently effective antigen. Control antigen was similarly prepared from normal mouse brain.

Patients received 0.1 cc. of antigen intradermally in the flexor surface of the left arm and the same quantity of the control in the right. Readings were made in two and three days. If the result was doubtful, patients were asked to make return visits for further observation. A reaction 7 mm. or more in diameter was considered positive. In the occasional patient giving a positive reaction to normal mouse brain, the test was repeated with human antigen. We preferred the mouse to the human antigen, as it was more constantly available and gave more consistent and more marked results.

Frei tests were performed on thirty-three persons with chronic ulcerative colitis with and without stricture and on one patient with proctitis. Of these, two, both having chronic ulcerative colitis without stricture, gave positive reactions, and the remaining thirty-two, including the patient with proctitis, gave negative reactions. Four patients with stenosing lesions of the large bowel with or without accompanying ulcerations were also given the Frei test and gave positive reactions. Data concerning the Frei positive group are presented in the table.

NEUTRALIZATION TESTS

The virus-neutralizing property of the serum of all the patients in this series was also studied. We are aware that the efficacy of the neutralization test in lymphogranuloma venereum is a controversial subject and have discussed this question in some detail in another paper.¹² It may be stated here, however, that we have found this test a very satisfactory diagnostic measure.

Technic.—As the source of virus, the brain of a mouse showing marked symptoms of lymphogranuloma venereum infection is removed, triturated well with salt solution and then centrifuged. The supernatant fluid is made up into serial dilutions from 1:10 to 1:10,000. To one volume of the various virus dilutions is added two volumes of inactivated serum. The mixtures are shaken, placed in the incubator at 37 C. for one hour and then left in the refrigerator at 4 C. over night, from sixteen to seventeen hours. Two weighed white mice are now inoculated intracerebrally with 0.03 cc. of each of the various mixtures. Mice are kept under observation for three weeks and weighed every two or three days.

Symptoms appeared in unprotected animals in from two to eight days, consisting of ruffling of the fur, arching of the back, tremors, ataxia, priapism, conjunctivitis, convulsions, cachexia and occasional paralysis. In protected animals symptoms failed to develop or else appeared after a prolonged incubation period.

Controls, with use of a known positive and known negative serum, were conducted with each series of test serums, and routine histologic and bacteriologic studies were made.

The serums of all six of the Frei positive patients previously mentioned showed repeated and consistent neutralizing properties against the virus of lymphogranuloma venereum. The serums of the remaining thirty-two patients, who were Frei negative, failed to show such properties.

The intradermal neutralization test in the guinea pig, as described by Wassen,¹³ also was used. This method, however, was not found to give as consistent results on the whole as the intracerebral test in mice, there being considerable variation in reactivity from one guinea pig to another.

ISOLATION OF VIRUS FROM TISSUES

As the Frei and neutralization tests merely demonstrate that there is, or has been at some time in the past, a lymphogranuloma venereum infection, we sought to clarify the relation of this condition to chronic ulcerative colitis by attempting to isolate the virus from the affected tissues. Biopsy specimens from active areas of the bowel were studied for this purpose.

Owing to the lability of the virus and the small amount of material available, we found it most practicable to inoculate animals directly. The bit of tissue, usually about 5 mm. in diameter, was ground well with 1 cc. of salt solution and the resulting emulsion sucked up into a tuberculin syringe. Six white mice were then inoculated intracerebrally with 0.03 cc. of the emulsion, and one guinea pig was inoculated subcutaneously in the groin with from 0.2 to 0.3 cc. Bacterial cultures were also made to determine the kind and amount of contamination present. Mice tolerated this treatment surprisingly well. Some had acute symptoms and died in from one to three days, at which time hemolytic and occasionally nonhemolytic *Bacillus coli* was cultured from the brain. The majority, however, were able to overcome the initial bacterial infection and either contracted later a more slowly evolving infection with the lymphogranuloma venereum virus or survived symptom free until killed at the end of two months for further study. The guinea pigs inoculated frequently developed subcutaneous abscesses from which a variety of cocci and bacilli were cultured. Occasionally a slight sterile lymphadenitis appeared, but we were never able

to recover virus from such nodes by passage to mice or other guinea pigs, nor were we able to prepare a satisfactory Frei antigen from them.

We were unable to isolate the virus of lymphogranuloma venereum by the described technic from either of the two Frei positive patients with typical chronic ulcerative colitis. Patient 1 was available for only one biopsy, but from patient 2 very satisfactory biopsies were obtained on three different occasions from active ulcerated areas of the bowel, showing considerable bleeding and exudation.

Of the four Frei positive patients with stenosing lesions of the large bowel with or without accompanying ulcerations, we were able to obtain lymphogranuloma venereum virus from two. Only one biopsy specimen was obtained from patient 4. This was taken shortly after the termination of a very successful course of treatment with sulfanilamide and was negative. From patient 5 two biopsy specimens were obtained, one of which gave negative results, the other proving unsatisfactory because of the presence of a hemolytic colon bacillus which killed all but one of the mice inoculated

to exist in a small percentage of cases of proved lymphogranuloma venereum but certainly cannot explain the negative results in so large a number. It is significant that our series included persons in all stages of the disease, from the acutely ill to those in whom there was apparent quiescence. The serum of six patients with negative Frei tests was tested both during a relatively inactive phase of the condition and during a subsequent flare-up with consistently negative results. On the other hand, serum from the six patients with positive Frei tests was repeatedly positive. It seems evident, therefore, that the condition of the patient at the time of bleeding could not account for the failure to observe neutralizing antibodies in the serum.

In the two Frei positive patients with chronic ulcerative colitis the relationship of the two conditions is difficult to evaluate. Our failure to isolate virus from the bowel lesions of these two patients, while suggestive, is not conclusive, in view of the difficulty encountered by ourselves and others in obtaining this virus from typical infections with lymphogranuloma venereum. Consideration also must be given to the possibility that

Significant Data for Six Frei Positive Patients with Various Disorders of the Large Bowel

Patient	Sex	Age	Race	Clinical Diagnosis	Proctoscopic Evidence	Frei Reaction	Neutralizing Power of Serum	Virus Isolations	
								Source of Biopsy	Result
1. F. B.	♂	39	White	Chronic ulcerative colitis	Numerous superficial ulcerations, no stricture	8 mm.	Positive	Ulcerated mucosa of rectum	Negative
2. M. G.	♀	28	White	Chronic ulcerative colitis	Granular bleeding mucosa, mucopurulent exudate, no stricture	7 mm.	Strongly positive	Ulcerated rectal mucosa Same 3 mo. later Same 1 mo. later	Negative Negative Negative
3. E. S.	♀	40	White	Rectal stricture with ulceration of the neighboring mucosa	Reddened granular mucosa, stricture 4-5 cm. from anal ring	10 mm.	Strongly positive	Ulcerated mucosa below stricture Same 5 mo. later	Negative Positive
4. L. P.	♂	40	White	Rectal stricture, regional colitis, colostomy	Friable bleeding mucosa, rectal stricture	12 mm.	Positive	Lower margin of stricture	Negative
5. P. H.	♀	50	White	Inflammatory stricture of sigmoid colon, benign rectal polyps, colostomy	Bleeding mucosa greenish yellow exudate, stricture 8 cm. from anal ring	7 mm.	Positive	Inflamed mucosa below stricture Same 13 mo. later	Negative Unsatisfactory
6. E. P.	♀	38	White	Rectal stricture	Smooth stricture 6.5 cm. from anal ring, no inflammation	9 mm.	Very strongly positive	Lower margin of stricture	Positive

within forty-eight hours. Of two biopsy specimens taken from patient 3, one gave negative results and the other yielded a highly virulent strain of the virus of lymphogranuloma venereum. We have maintained this strain for nine passages in mice and find that it cross immunizes with the strain previously isolated by us from a frank inguinal lymphadenitis. Frei antigen prepared with this strain gave positive Frei reactions in two known cases of lymphogranuloma venereum and negative results in three controls. A single biopsy specimen from the lower end of the stricture in case 6 yielded a strain of the virus of lymphogranuloma venereum of relatively low pathogenicity for mice. Symptoms appeared in two of six mice thirty days after injection. The strain died out after two passages but yielded satisfactory Frei antigen, as indicated by the production of positive Frei reactions in three cases of lymphogranuloma venereum and negative reactions in three controls.

COMMENT

The fact that thirty-two out of thirty-four patients (94 per cent) with chronic ulcerative colitis and proctitis in this series had negative Frei tests and showed no evidence of neutralizing antibodies in their serums against the virus of lymphogranuloma venereum indicates that this virus was in no way involved in the great majority of cases. A state of anergy has been shown

the virus, although not directly responsible for the bowel ulcerations, may have paved the way for other necrotizing agents to become established by producing a lymph stasis, as Frei originally suggested. In this connection it may be significant that Dack and his co-workers¹⁴ have isolated *Bacterium necrophorum* from all of these patients. Attention may also be called to a certain similarity in the proctoscopic picture between some lymphogranuloma venereum infections of the large bowel and chronic ulcerative colitis, especially well illustrated in our series by case 3, which may occasionally cause confusion in the differential diagnosis.

SUMMARY

Thirty-one patients with chronic ulcerative colitis and one with proctitis gave negative Frei reactions and did not possess neutralizing antibodies against the virus of lymphogranuloma venereum in their serums. Two patients with ulcerative colitis and four with stenosing lesions of the large bowel with or without accompanying ulceration, when similarly tested, gave positive results.

The virus of lymphogranuloma venereum was isolated from two of the Frei positive patients with rectal stricture.

CONCLUSION

Lymphogranuloma venereum and nonspecific ulcerative colitis are independent diseases which, in their early stages, may resemble each other clinically and proctoscopically.

The six cases in which positive Frei tests were obtained are here summarized:

CASE 1.—F. B., a man aged 39, first seen in the gastrointestinal clinic in 1932, had had a diarrhea of six years' duration. The onset of illness had been sudden with the passage of bloody, liquid movements. Examination elsewhere disclosed no evidence of parasitic infection. Treatment had included emetine, calcium carbonate, belladonna, acetarsone, silver nitrate enemas and various forms of vaccine therapy.

Proctoscopic examination revealed an injected bowel mucosa with numerous superficial undermined ulcerations of various sizes: a picture not unlike that seen in amebic dysentery. X-ray studies demonstrated a small colon devoid of haustra, the rectum was narrowed and, on mucosal films, the mucosa of part of the transverse colon and superior descending portion was swollen.

On many examinations the blood and urine were normal. Wassermann and Kahn tests were negative. Repeated search for amebas in the stools and many stool cultures were consistently negative. Agglutination studies were also negative.

Treatment included the use of sedatives, tincture of belladonna and a bland, low residue diet. Very mild improvement followed the use of Bagen's serum. Numerous proctoscopic examinations by several observers were interpreted as showing various phases of a chronic nonspecific ulcerative colitis. When last examined, the rectal mucosa was reddened with several areas of punctate bleeding.

CASE 2.—M. G., a woman aged 28, entered the University of Chicago Clinics complaining of rectal bleeding which had lasted three years. Bowel movements were hard and there was much flatulence. Treatment by a local physician consisted of tannic acid enemas daily.

She had been treated for a Bartholin cyst infection a year and a half previously; the lymph nodes on the corresponding side were swollen and tender. One month later a recurrence of this infection again required incision and drainage.

Physical examination was essentially negative. Results of laboratory studies were normal. Agglutination tests for typhoid, paratyphoid and dysentery were negative. X-ray examination revealed a normal colon and terminal ileum. Proctoscopically the mucosa of the rectum and sigmoid was inflamed and granular and bled easily. There was a moderate mucopurulent exudate. The appearance was considered typical of chronic nonspecific ulcerative colitis.

Treatment included sulfanilamide up to 80 grains (5 Gm.) daily, cod liver oil retention enemas, azosulfamide up to 80 grains daily, nicotinic acid 80 mg. daily, sedatives and a bland diet. The patient's condition has remained essentially unchanged.

CASE 3.—E. S., a woman aged 40, was first seen in 1931 with bleeding from the rectum, which had continued for several years. She had been treated many years for arthritis involving the hands, knees and shoulders. Proctoscopic examination disclosed a reddened granular mucosa with several small superficial ulcerated areas; a fibrous band narrowed the ampulla. X-ray studies revealed a narrowed rectal ampulla, with absence of haustra in the descending colon. There was moderate secondary anemia.

Cultures and examinations of the stools for parasites were negative. Agglutination tests for typhoid, paratyphoid and dysentery were negative. The patient's course during the next nine years was variable. In 1933 a definite anal stricture at a level of 4 or 5 cm. was noted; the mucosa was granular and friable. Treatment included a series of injections with Bagen's serum, sulfanilamide and azosulfamide. Hospitalization was required for the treatment of perianal and ischioanal abscesses and excision of a fistula in ano. The patient has continued on a program including a nonlaxative, low residue diet with sedatives, tincture of belladonna and thiamine hydrochloride. Recently there has been a decrease in the number of stools and the patient has improved subjectively.

CASE 4.—L. P., a man aged 40, was first seen in the University of Chicago Clinics in November 1933 with bloody diarrhea and rectal tenderness. In 1926 he had a penile sore treated with intramuscular injections. In 1928 another penile sore, associated with a sore throat and joint pains, was treated with intravenous and intramuscular injections. A positive serologic reaction was reported at this time. In February 1933 a draining rectal fistula was surgically treated elsewhere. Two Wassermann and Kahn tests as well as a spinal fluid examination were negative. No parasites were found in the stools, and repeated cultures were negative. Rectal examination disclosed the scars of healed fistulas; a marked stricture was palpable, and on proctoscopic examination the rectal mucosa was friable and granular.

Between April 3 and Oct. 13, 1934, the patient was treated with antimony and potassium tartrate, receiving from 3 to 10 cc. of a 1 per cent solution intravenously in three courses of ten injections each. Frequent dilations of the rectal stricture were necessary. In October the inguinal nodes on the left side were swollen and tender.

In June 1936, 8 inches of transverse colon was resected at the Mayo Clinic because of a regional colitis. In December 1937 a colostomy was performed because of obstruction. At this time an inflammatory mass was felt in the rectum and a similar mass involved the left portion of the transverse colon. He was subsequently treated with sulfanilamide, 60 grains (4 Gm.) daily. The purulent discharge from the colostomy stopped and the patient gained 50 pounds (23 Kg.). When last seen, he was in good general health. On proctoscopic examination the rectal mucosa was still definitely inflamed; the stricture was unchanged.

CASE 5.—P. H., a woman aged 50, entered the University of Chicago Clinics with lower abdominal pain, malaise and diarrhea and "discharge of pus from the rectum," which had been present four or five weeks. The onset of illness had been sudden, with chills and a fever rising to 103 F. There had been a loss of 22 pounds (10 Kg.) during this time. Inquiry revealed probable gonorrheal infection two years previously, treated by injections and vaginal douches.

Physical examination was negative except for the presence of a second degree cystocele, a lacerated cervix and apparent fixation of the pelvic structures. Rectal examination revealed an obstruction at a level of 8 cm. from the anal ring and a large indurated mass on the anterior wall of the rectum. On proctoscopic examination the rectal mucosa bled easily, a thick, greenish yellow exudate was noted, and several small polypoid areas were found. Roentgenograms revealed a lesion constricting the upper portion of the rectum, probably neoplastic.

Laboratory studies revealed a moderate secondary anemia; Wassermann and Kahn tests were negative. Agglutination tests for typhoid, paratyphoid, and Sonne and Flexner dysentery were negative.

Three biopsies of the polypoid area disclosed no evidence of neoplasm. A Frei test performed in 1938 with a commercial antigen was negative. A colostomy was performed because of the obstruction. It was noted that there was a large inflammatory mass in the pelvis fixing the sigmoid colon, uterus and tubes in one mass. The sigmoid for a distance of 6 inches proximal to the mass was thickened, its wall edematous and covered with a filmy exudate. There were no enlarged lymph nodes. The patient made an uneventful recovery and subsequently was treated with sulfanilamide given orally and in retention enemas. Her course has been quite satisfactory. The rectal discharge has diminished markedly and the mucosal inflammation has disappeared.

CASE 6.—E. P., a woman aged 38, was referred to the gastrointestinal clinic for proctoscopic examination. She stated that thirteen years previously a rectal stricture had been dilated at another hospital in the city and that subsequently frequent such dilations were necessary. Two years previously treatment was required for a Bartholin's abscess on the right side. She stated that she had no venereal infection, and several serologic studies were reported negative. Several months ago she began to complain of transient sharp burning pains in the lower mid-abdominal region accompanied by a sense of pressure in the rectum. Pelvic examination revealed an elongated tender mass on the left side with evidence of induration in the right tubo-

ovarian region. Proctoscopic examination disclosed a smooth stricture 6.5 cm. from the anal ring, the lumen wide enough to admit a finger tip.

X-ray studies were interpreted as demonstrating an unusual narrowing of the rectal ampulla and sigmoid.

Laboratory studies were negative. The patient at the present time is being treated in the gynecology clinic for the pelvic infection.

VITAMIN P IN VASCULAR PURPURA

I. NEWTON KUGELMASS, M.D.

NEW YORK

CHEMISTRY OF VITAMIN P

Vitamin P was postulated by Szent-Györgyi¹ as a regulator of vascular permeability, isolated in crystalline form as a flavone glucoside from lemon juice and named citrin to indicate its chemistry. It was found to consist of mixed crystals of two related flavone dyes, the glucoside hesperidin $C_{30}H_{40}O_{27}$ and the glucoside of eriodictyol; the former constitutes the major part of citrin but the latter is responsible for the chemical reactivity and color production. The glucosides of citrin are but two forms of the same flavonone glucoside, the eriodictyol glucoside being formed from hesperidin by demethylation during ripening of citrus fruits, particularly lemon, orange and grapefruit.

Citrin forms light yellow crystals sparingly soluble in water but very soluble in alkali, giving intense yellow solutions. The relative composition of the solid and liquid phases, respectively, is determined by the solubility of its two components; the crystals consist mostly of insoluble hesperidin and small amounts of soluble eriodictyol, while the solutions consist mostly of eriodictyol glucoside and traces of hesperidin. These glucosides are well tolerated in doses of several hundred milligrams, retained in variable amounts by the body and readily recovered in the urine.

The flavones are a class of naturally occurring yellow plant pigment, phenyl derivatives of the 1,4-pyrone or γ -pyrone nucleus. The intensity of the color depends greatly on the position of the hydroxyl groups and is most pronounced if two are ortho in position to each other. The pigments occur in plants as glycosides, one or more hydroxyl groups being combined with a sugar molecule. The formula may be expressed by sugar-O-R, where R represents the flavone group attached to carbon —1 of the sugar, usually dextrose. This renders the auxochrome group inactive so that in the plant the flavone glycosides are practically colorless until they are hydrolyzed and the characteristic yellow develops.

The role of glycosides in plants has been interpreted as a mechanism whereby the substances which have great physical activity are held inert until they are needed in the metabolism of the plant or in detoxifying poisonous substances so that they will not injure plant cells. It is possible that the latter mechanism maintains these substances for protecting the functional integrity of the vascular endothelial system in man,² demonstrated in vascular purpura. These glycosides are usually levorotatory, crystalline, colorless, bitter and soluble in water.

CAPILLARY RESISTANCE OF CHILDHOOD

Capillary resistance varies with age and nutritional status. During the first few weeks of life an infant shows the highest level of capillary resistance, manifested uniformly throughout the body to the extent of about 500 mm. of mercury. This gradually diminishes during infancy until the adult level is attained, approximating about 150 mm. of mercury. There are marked fluctuations, however, not only in the level of capillary resistance but also in various sites of the body, the values increasing from a minimum at the head to a maximum at the extremities in the same child. The variations in capillary resistance with age and site reveal the remarkable adaptation of the body to environmental offense.

Capillary resistance may be measured by tourniquet, intradermal venule, graded suction or positive pressure tests; the first is a simple qualitative index of vascular status, the second a pseudoquantitative impractical measure and the third and fourth fairly accurate measures used in this study. When cutaneous purpuric spots do not occur spontaneously they may be induced in susceptible children by any of these methods. The negative pressure method is most accurate but was not particularly adapted for clinical routine with children. The positive pressure method determines fragility in terms of the number of ruptured capillaries developing under standard conditions in response to increased intracapillary pressure maintained for five minutes.

Capillary tonus decreases in vascular hemorrhagic diseases³ with escape of normal blood from a weakened capillary bed or vascular endothelium as a result of trauma, pressure, avitaminosis, bacterial invasion, chemical injury or lymphatic infiltration. The vast surface of the minute capillaries thus becomes weakened by mechanical injury exceeding the normal tension at that site by nutrient deficiency leading to inadequate endothelial repair, by sensitization to substances allergenic to susceptible children, by interaction of bacterial toxins with vascular structures, by precipitation of bacterial emboli and by actual chemical destruction of capillary cells.

The value of yellow benzopyrane dyes or group of flavones in restoring resistance to damaged capillaries has been determined in cases of vascular hemorrhagic diseases showing normal levels of blood-clotting constituents. Preliminary tests indicated that citrin does not alter the concentration of any of the blood components involving clotting—fibrinogen, prothrombin or platelets—in normal children or in those affected with hemorrhagic disease. With the alleged therapeutic specificity of the flavones it became a relatively simple procedure to determine their value in nutritional, allergic, infectious and toxic diseases characterized by vascular bleeding. The vitamin material was prepared commercially from orange peel according to the method of Szent-Györgyi.⁴ The solution of 50 mg. per cubic centimeter of flavonones consisting of eriodictyol glucoside and hesperidin was given in doses of 150 mg. orally. Although the number of cases reported is very limited they were clearcut, permitting the first approximation of the merits of vitamin P in vascular bleeding.

REPORT OF CASES

Nutritional Purpura.—J. T., a dystrophic dehydrated white boy of 5 months weighing 6½ pounds (2,948 Gm.), suddenly developed small discrete purpuric spots over the abdomen and

4. Szent-Györgyi, Albert: *Ztschr. f. physiol. Chem.* 255: 126, 1938.

Read before the Brooklyn Medical Society and the New Jersey Medical Society.

1. Armentano, L.; Benthath, A.; Béres, T.; Rusznayk, Istvan, and Szent-Györgyi, Albert: *Deutsche med. Wchnschr.* 62: 1325 (Aug. 14) 1936.

2. Scarborough, Harold: *Biochem. J.* 33: 1400 (Sept.) 1939.

lower extremities. The infant was premature, weighed 4 pounds (1,814 Gm.) at birth and failed to thrive on breast feeding, proprietary mixtures and cow's milk modifications. The infant responded to parenteral fluids, blood transfusion and gradually increasing amounts of lactic acid milk with 10 per cent added carbohydrate. The purpura diminished with clearance of the diarrhea but cleared more rapidly when the vitamin P mixture was given. The number of punctate hemorrhages induced by the positive pressure test for capillary resistance during the course of treatment indicates the effectiveness of the vascular vitamin:

Day	5	10	15	20	25	30
Petechiae	51	45	35	30	5	5
Treatment	Transfusion		Vitamin C		Vitamin P	

Allergic Purpura.—C. H., a 10 year girl of allergic constitution, had high fever, recurrent chills, abdominal pain and bloody stools. The child appeared septic, with no other abnormalities, and was considered suffering from the current intestinal infection. The blood showed 72 per cent hemoglobin, 4,100,000 red cells and 10,500 white cells, with 42 per cent polymorphonuclears, 50 per cent lymphocytes, 7 per cent eosinophils and 1 per cent basophils. On the following day the right ankle swelled, purpuric spots developed over the extremities, and the right knee and left ankle also became affected. The symptoms cleared spontaneously within a week, but the purpura persisted. Positive pressure tests of capillary resistance to determine the relative merits of 10 per cent calcium gluconate and vitamin P mixture indicated the superiority of the latter in improving vascular function:

Day	5	10	15	20	25	30
Petechiae	115	90	45	30	45	22
Treatment	Calcium		Vitamin P		0	Vitamin P

M. C., a 15 year old allergic girl, had recurrent cutaneous hemorrhages associated with nosebleeds, high fever, occasional chills, abdominal pain and persistent diarrhea with mucus and blood. The intestinal spasm was aggravated by ingestion of egg white, wheat, alcohol, cinchophen and phenobarbital, as corroborated by positive cutaneous tests. The blood picture varied in leukocytic response with a tendency to lymphocytosis. The clotting components were normal in concentration, the clotting time was normal, bleeding time normal and tourniquet test positive. The condition abated with elimination of offending allergens, but purpuric manifestations continued. Sulfanilamide therapy cleared most of the symptoms except the purpura. Vitamin P mixture given thereafter resulted in arrest of cutaneous hemorrhage and decrease in the number of petechiae following positive pressure determinations:

Day	5	10	15	20	25
Petechiae	120	80	95	20	15
Treatment	Allergen elimination		Sulfanilamide		Vitamin P

Infectious Purpura.—K. B., a 9 year old girl, had abdominal pain, high fever and purpura over the lower extremities within a week of recovery from scarlet fever. A fresh crop of purpura appeared daily for a week, extending upward to the trunk, arms, palate and conjunctivas. There was no hematuria or other evidence of nephritis despite the destructive effect of scarlet fever toxin on the glomerular endothelium. Positive pressure tests of capillary resistance showed favorable effects from daily administration of vitamin P solution:

Day	5	10	15	20	25	30
Petechiae	96	50	92	41	55	30
Treatment	Vitamin P		0	Vitamin P		Vitamin P

Mechanical Purpura.—P. A., a 9 year old boy, had petechiae in the conjunctivas and eyelids during whooping cough. G. A., a 16 year old mentally retarded boy with epilepsy, occasionally

showed purpuric extravasations following severe seizures resulting from water-guzzling bouts during a ketogenic regimen. H. B., a 10 year old girl with Perthe's disease, showed orthostatic purpura when plaster of paris casts were removed and the child was allowed freedom of activity. In each of these cases the daily administration of vitamin P solution failed to show any change in the number of petechiae demonstrated by positive pressure test.

SUMMARY

A solution of eriodictyol glucoside and hesperidin, vitamin P concentrate, administered orally was effective in treatment of two children with allergic purpura, a child with infectious purpura and an infant with nutritional purpura, and ineffective in three cases of mechanical purpura. Vitamin P constitutes another valuable adjuvant in the management of vascular purpura, provided the underlying cause is cleared.

Clinical Notes, Suggestions and New Instruments

ENDOMETRIOSIS OF THE ILEUM WITH CHRONIC PARTIAL INTESTINAL OBSTRUCTION

PAUL M. GLENN, M.D., AND JOHN J. THORNTON, M.D.
CLEVELAND

Endometriosis is not an uncommon condition. Sampson is quoted as seeing it 101 times in 474 gynecologic operations and Green-Armytage in 8.9 per cent of 1,000 surgical cases.¹ In this hospital endometrial implants are found in about 10 per cent of pelvic operations.² Regarding the organs involved, figures from the Mayo Clinic³ state that 689 organs of 576 patients were involved with this diagnosis. These were mostly pelvic genital organs, and the intestine was involved in only seventeen instances. In these instances the sigmoid flexure of the colon was the site of endometrial implants in fourteen cases, the appendix in one and the ileum in two cases. Keene and Kimbrough⁴ did not find the small intestine involved in any of 118 proved cases, nor did Cullen⁵ in reporting personal observations over a twenty-five year period.

Endometrial implants in the ileum, therefore, appear to be an unusual occurrence. Such a lesion producing small intestinal obstruction is a rarity, although obstruction of the lower portion of the bowel by growth of endometrium in the rectovaginal septum is well known. Review of the English literature for the past twenty years reveals only four cases⁶ of endometrial implants in the small intestine with some degree of obstruction present.

The true incidence of endometrial implants in the small intestine, however, is unknown. They are not looked for in a routine way on that organ in gynecologic operations. In rare instances an implant in the small intestine is an incidental finding at operation, or it may be the causative lesion producing intestinal symptoms which is discovered at operation.

Because of the apparent rarity of this condition, the following cases seem worthy of being reported.

REPORT OF CASES

CASE 1.—A white woman aged 31 entered the hospital complaining of "stomach trouble." The past history revealed that she had generally enjoyed good health. After the menarche at the age of 12 she had cramps in the lower portion of the abdomen during the menses for a few years. Five years before admission she had an (induced?) abortion, followed by profuse leukorrhea and frequent attacks of pain in the lower abdomen for about eight months. She had no other pregnancies.

The present illness began about one year before admission with an occasional feeling of fullness and vague abdominal distress after meals. This was attributed to various foods, which were eliminated from her diet without relief. The attacks increased in severity and duration. They were then characterized by cramplike pain starting in the midportion of the abdomen on the right and radiating to the left side, occasional nausea and vomiting, constipation and some abdominal distention. Between attacks she found it necessary to use laxatives frequently because of increasing constipation. About eight months before admission she first noted that the attacks were usually associated with her menstrual periods. By limiting her diet to liquid and soft foods during her menses the severity of attacks was ameliorated, but gradually this curtailment became less

It was believed that the patient suffered from chronic partial intestinal obstruction as a result of adhesions from an old pelvic inflammatory disease. Because of the long history, the marked distention and the poor general condition of the patient it was decided to use the Miller-Abbott intestinal tube⁷ to decompress the intestine, improve the condition of the patient for operation

Fig. 1.—Appearance of lesion: a, sacro-iliac joint; b, ilium bone; d, terminal ileum; e, area of constriction; f, dilated ileum; g, Miller-Abbott tube.

effective. For four months the attacks had been quite severe and their duration had increased to from seven to ten days. The last attack began six weeks before admission and persisted until she entered the hospital. During this interval she was never entirely free of symptoms, though there were brief periods of relief from pain, vomiting, constipation and distention following the use of laxatives and enemas. During the year before admission she had lost more than 15 pounds (6.8 Kg.).

The patient was undernourished and chronically ill and she weighed 80½ pounds (36.5 Kg.). Positive manifestations were limited to the abdomen, which was considerably distended and tympanic, although peristalsis was visible. Borborygmi were frequently audible and coincided with exacerbations of the abdominal pain. Vaginal examination revealed induration in both adnexal regions.

Temperature, pulse, respirations and blood pressure were normal. Laboratory data showed 9,450 white blood cells with a normal differential count, 4.52 million red blood cells, 80 per cent hemoglobin (Sahli), a negative reaction to the Kline exclusion test, blood urea nitrogen 18.5 per hundred cubic centimeters, plasma chlorides 614 mg. and carbon dioxide combining power 44.8 volumes per cent. The sedimentation rate was normal and analysis of the urine negative.

Roentgenograms of the abdomen showed numerous distended intestinal loops with a "ladder" pattern. An enema of barium sulfate did not reveal a colonic lesion.

Fig. 2.—Location of lesion shown in figure 1.

and possibly aid in establishing a more accurate diagnosis. Prompt symptomatic relief and marked improvement of the distention followed the intestinal intubation. Within twenty-four hours the tube had advanced sufficiently for the patient to take adequate fluids, chloride and food⁸ orally.

The advance of the tube through the lower portion of the ileum was quite slow, but the tip finally stopped in the terminal ileum. Injection of a thin suspension of barium sulfate through the tube showed a narrowed area in the terminal ileum about 12 cm. from the cecum (figs. 1 and 2), which the roentgenologist believed was due to an adhesion. Ileum proximal to the narrowed area was still somewhat dilated in spite of constant drainage of the intestine for the preceding seven days. That

Fig. 3.—Gross appearance of the constricting lesion. The arrow points to two grossly apparent dark purple nodules of endometrial tissue.

the dilated intestine was not paralyzed was evident, because kymographic records showed it to have activity of the type found just proximal to an area of obstruction.⁹

7. Abbott, W. O.: Intubation of the Human Small Intestine: XII. The Treatment of Intestinal Obstruction and a Procedure for Identifying the Lesion, *Arch. Int. Med.* 63: 453 (March) 1939.

8. Noer, R. J., and Johnston, C. G.: Decompression of the Small Bowel in Intestinal Obstruction, *Am. J. Digest. Dis.* 6: 46 (March) 1939.

9. Abbott, W. O.; Zetzel, Louis, and Glenn, P. M.: Observations on the Motor Activity of the Obstructed Small Intestine Made During the Course of Treatment, *Am. J. M. Sc.* 195: 279 (Feb.) 1938.

After twelve days with the intestinal tube in place, during which time the patient had a daily dietary intake of 2,200 calories the residue of which was drained at the point of obstruction, she was in much better condition for operation. At operation about 3 feet of the terminal ileum had a thick wall and was slightly dilated. The tip of the intestinal tube was in this segment. About 15 cm. proximal to the ileocecal valve the thickening and dilatation of the ileum ended abruptly in a moderately firm, sharply circumscribed, reddish purple area of constriction. The lesion was entirely free from all surrounding structures and the serosa was intact and glistening everywhere except at the center of the lesion, where there was a dark purple nodule measuring 2 or 3 mm. in diameter. No abnormality was noted elsewhere in the intestine. No endometrial implants were noted in the pelvis, but a detailed inspection was impossible because both tubes and ovaries showed evidence of rather extensive chronic inflammation with numerous adhesions. It was decided not to attempt any pelvic surgery because the principal lesion was in the intestine.

The constricting lesion and ileum distal to it were removed and an end to side ileocecostomy was done. The postoperative course was entirely uneventful. The intestinal tube was left in place and constant suction was maintained to keep the intestine emptied at the suture line. Oral intake was started on the second postoperative day. Intestinal drainage was discontinued

Fig. 4.—Section under high power, showing endometrial implants in muscularis of ileum.

on the fifth postoperative day without evidence of obstruction and the tube was removed on the seventh day. Convalescence continued uneventfully and follow-up observation for five months has shown no clinical or roentgenologic evidence of obstruction. She now weighs 97 pounds (44 Kg.), which is more than she has ever weighed.

CASE 2.—A white woman aged 50, a patient of Dr. A. J. Beams, made presenting complaints that were almost identical to those in case 1 except that her story was of two years' duration. Preoperative management was also similar to that in the first case but the diagnosis of endometriosis of the ileum was made preoperatively. The gross appearance of the lesion, which was in the same location as the lesion in the first case, is shown in figure 3.

Microscopic examination of both of the lesions (fig. 4) showed intact intestinal mucosa. There were numerous islands of endometrial tissue throughout the muscularis, and fibrosis and focal lymphocytic infiltration of the muscularis and serosa. It is very probable that the inflammatory reaction which usually accompanies endometrial implants resulted in fibrosis, with progressive constriction of the lumen of the ileum.

The periodicity of the symptoms of intestinal obstruction in association with the menses was probably due to the hyperplastic reaction of the endometrial tissue at such times with a greater degree of obstruction to the lumen of the ileum than between the menses when the endometrial tissue was in the resting stage. The reaction was progressive until the lumen of the ileum was constricted sufficiently to produce continuous symptoms.

CONCLUSIONS

1. In the cases here presented endometrial implants in the terminal ileum produced chronic partial intestinal obstruction.
2. The preoperative use of the Miller-Abbott intestinal tube was valuable (a) in controlling the symptoms of intestinal obstruction while the patient's condition was being improved for operation, (b) in accurately localizing the point of obstruction and (c) in simplifying the technical aspects of the operative procedure.

PULMONARY COMPLICATIONS DURING PREGNANCY

MILTON G. POTTER, M.D., BUFFALO

When considering diseases of the lungs during pregnancy, one must remember that there are certain normal physical changes and signs in the chest due to pregnancy.

As the growth of the uterus continues there is slight congestion of the lungs with an increased lateral expansion, the excursion of the diaphragm is decreased and the breathing becomes more costal. These changes are, as a rule, more pronounced in the primipara than in the multipara, because there is less relaxation of the abdominal muscles in the former.

It becomes immediately apparent, therefore, that such conditions bring about an ideal nidus for the harboring of infection and explains somewhat the reason why quiescent infections in the lungs may be activated.

This is particularly true of women with arrested pulmonary tuberculosis who become pregnant.

It is an astounding fact that approximately 50,000 women in the child-bearing period die each year from tuberculosis and that a total of 32,000 tuberculous women become pregnant each year in the United States.

This condition places a terrific burden of responsibility on the medical profession, for while there are certain generalities on which there is universal agreement, the question of treatment, unfortunately, is highly individualized.

Every one is pretty well agreed that matrimony in the presence of active pulmonary tuberculosis should be forbidden, for it aggravates the disease, may infect the husband and propagates tuberculous children.

It is also agreed that the strain of pregnancy and lactation add to the risk of reactivation of a quiescent tuberculous process.

While it is conceivable that pregnancy may be permitted for women whose tuberculosis has been in the quiescent stage for a period of two years or more, one can never tell when the latent disease may again become florid. One must remember that often no untoward effects are observed until the puerperium, at which time the disease flares up and resembles pneumonia more than tuberculosis. Pregnancy definitely aggravates the disease.

Unfortunately the obstetrician's advice concerning matrimony is seldom sought and he does not come into the picture until after the marriage.

If the patient has not conceived, contraceptive advice should be given. If the patient is pregnant and her tuberculous condition has been quiescent, it is proper for the physician to allow the pregnancy to continue. It is my belief and my practice that if the tuberculous process is reactivated before the fifth month abortion should be induced. In the late months of pregnancy, however, nonintervention should be the rule, as the risk of delivery is no greater than a therapeutic abortion.

If the pregnancy is allowed to continue, the patient should receive every dietary and hygienic attention accorded the non-pregnant person, and the cooperative help of an internist is not only desirable in the treatment of this complication but necessary.

A potential tuberculous patient should have as short a labor as possible, and intervention to shorten or obliterate the second stage of labor, under local or spinal anesthesia, is proper. Lactation should be prohibited, the baby separated from its mother and, if repeated pregnancies occur, sterilization should be recommended.

Another pulmonary complication during pregnancy is pneumonia. It may be of any of the types seen in the nonpregnant person, such as bronchial, lobar or influenzal. Regardless of

From the Obstetrical Department of the Millard Fillmore Hospital.

the type, the condition is most serious and in 50 per cent of the cases the onset is usually manifested by a feeling of malaise, stuffiness in the head, sore throat, a slight rise in temperature, with or without pain in the chest, and gastrointestinal disturbances.

Whether this group of symptoms is called grip or a common cold at the onset is immaterial. The fact remains that a pregnant woman with this syndrome should have the serious consideration of the physician in charge and treatment should be instituted immediately. It has been my observation that too often the physician considers this condition lightly and allows what might have been a mild attack to progress into one of the more serious types of pulmonary infection.

It must be remembered that we are dealing with a person whose natural resistance and phagocytosis is lowered by her pregnancy, which also has produced an increased congestion in her lungs. This combination of circumstances makes the respiratory tract a fertile field for continued growth of pathogenic organisms and, unless checked, will produce serious consequences for mother and baby.

It is my belief that in this combination of circumstances a bacteremia is more common than is generally realized and, if one is dealing with virulent organisms, the end results can be most disastrous, even though one institutes as complete therapy as possible.

Some years ago, during an epidemic of so-called influenza, I instituted the practice of taking cultures from the nose and throat of every pregnant private patient who was suffering with what was considered the grip. The following reports of cases, I think, will help to prove the point I am trying to make, namely that bacteremia is present more times than is generally realized and not infrequently dire results are noted in either mother or baby or both.

REPORT OF CASES

CASE 1.—Mrs. A. complained of sore throat, cough, general malaise and a severe backache. She expelled a mass which included the placenta with a five months fetus within the amniotic sac; this was sent to the laboratory and examined by the late Dr. Benjamin Roman, pathologist at the Buffalo General Hospital. Culture of the mother's throat revealed many influenza bacilli, and the same organisms were recovered from the fetus. The patient recovered.

CASE 2.—Mrs. B., a secundipara aged 33, had severe nausea with both pregnancies. In the fourth month of the second pregnancy she became ill with a so-called grip infection, which lasted for ten days. At the end of this time she started in labor and passed a four months fetus and a placenta. These specimens were sent to the laboratory for examination. A pure culture of pneumococci was found in the lungs and heart of the fetus and the identical organism was recovered from the patient's nose and throat. The patient recovered.

CASE 3.—Mrs. B., a primipara five months pregnant, previous to admission to the Children's Hospital had a history of grip and some vaginal flow for two weeks. On admission she had an elevated temperature, symptoms of grip, a bloody vaginal discharge, a cervix admitting two fingers and irregular labor pains. Several hours after the vagina had been packed the patient was delivered of twin boys, who lived fifteen minutes. The placenta was most friable and adherent and was finally removed manually in sections. The fetus and placenta were sent to the laboratory for culture. Streptococci were recovered and the same strain was obtained from the mother's throat. The patient recovered.

CASE 4.—Mrs. H., a secundipara aged 35, six months pregnant, contracted what was considered an ordinary head cold. Her family physician treated her for a period of one week. No abnormal chest signs were evident during the entire sickness except slightly diminished respiratory sounds. After the third day of her illness she became cyanotic and irrational and oxygen was administered continuously. The heart action, for the most part, continued to be slow, regular and of good volume. On the sixth day of her illness she went into labor (lasting two hours) and expelled a six months living fetus. After delivery of the placenta she went into shock, the pulse became very faint and rapid and cyanosis became more pronounced. Twelve hours after expulsion of the fetus the mother

died and after fifteen hours the baby died. Bacterial examination revealed organisms in the mother's nose and throat identical with those in the organs of the fetus.

CASE 5.—Mrs. X, two weeks before the onset of labor, contracted a sore throat, coryza and general malaise. An almost pure culture of streptococcus was obtained from the throat. Her general condition did not improve greatly until after the delivery of her child. She gave birth to a male child who appeared normal in every respect. The delivery was not remarkable. Twenty-four hours later the baby was found dead in his crib. At autopsy the lungs were in the red stage of hepatization and the liver and spleen were soft and friable. Nothing else of note was found. Cultures from the liver and spleen yielded the same strain of streptococcus as was previously obtained from the mother's throat.

COMMENT

The cases here reported and their histories impressed me tremendously and taught me that even in the presence of adequate antepartum and medical care disastrous results may be expected when the respiratory tract of a pregnant woman is infected with virulent organisms.

PANTOTHENIC ACID IN HUMAN NUTRITION

T. D. SPIES, M.D., CINCINNATI; S. R. STANBERRY, M.A.,
BIRMINGHAM, ALA.; R. J. WILLIAMS, PH.D., AUSTIN,
TEXAS; T. H. JUKES, PH.D., AND S. H.
BARCOCK, PH.D., BERKELEY, CALIF.

The syndrome resulting from a lack of pantothenic acid in the diet of the chick and the rat has been described¹ and the recent synthesis of pantothenic acid² has made this substance available in pure form for clinical studies. Since there was no information regarding the possible toxicity of this substance in human beings, we administered varying amounts of calcium or sodium pantothenate to fifteen people and observed that 100 mg. of either salt may be injected intravenously without causing a reaction and without significant change in blood pressure, pulse, temperature and respiration.

In making these observations we assayed the blood and urine for pantothenic acid³ before and at intervals after injection. We found that the pantothenic acid content of the blood increases up to 50 per cent above the preinjection level and that this increase is noted within the first three hours after the injection but that in all instances the value returns to its previous level within twenty-four hours. Urine specimens showed an increased pantothenic acid concentration immediately following the injection, but this also returned to normal within twenty-four hours. The blood pantothenic acid concentration of twenty-eight patients with pellagra, beriberi and riboflavin deficiency was decreased from 23 to 50 per cent, as compared with the levels of eighteen normal persons.

Using a similar technic⁴ we have assayed this same blood for riboflavin and have found that following the injection of

pantothenic acid there likewise is a rise of from 20 to 30 per cent in the riboflavin level of the blood. The administration of 20 mg. of calcium pantothenate daily, for four days, to four persons with cheilosis and typical ocular manifestations diagnostic of riboflavin deficiency caused similar temporary increases in the blood pantothenic acid and riboflavin. These values, however, returned to their previous levels when therapy was discontinued.

We have found that the injection of 200 micrograms of riboflavin per kilogram of body weight caused an increase of 80 per cent in the blood flavin concentration and of 45 per cent in the pantothenic acid level. While these values remained high for from three to four hours, they returned in each instance to the former level by the next day.

These observations indicate that pantothenic acid is essential to human nutrition and that its function is probably associated with that of riboflavin.

Special Clinical Article

THE DIAGNOSIS OF HEART FAILURE

CLINICAL LECTURE AT NEW YORK SESSION

TINSLEY R. HARRISON, M.D.

NASHVILLE, TENN.

Heart failure is of two general types, which may be conveniently designated as forward and backward failure respectively. Forward failure, which is characterized by inability, usually setting in suddenly, of the heart to supply an adequate amount of blood to the body tissues, may be subdivided into (a) sudden death (usually brought about by ventricular fibrillation), (b) cardiac syncope (which is commonly due to sudden slowing of the heart) and (c) cardiac collapse (which may be induced by extreme tachycardia, by acute myocardial injury or by sudden hindrance to the heart in carrying out its work). In all these conditions the chief clinical symptoms are those referable to the central nervous system and are brought on by a deficiency of the blood supply to this vital area, the severity of the symptoms depending on the degree and the rapidity of onset of the circulatory deficiency to the brain.

Backward failure of the heart, on the other hand, occurs when, because of an excessive load or advanced disease of the musculature or (more commonly) because of a combination of these two factors, the degree of ventricular dilatation becomes sufficient to impose an impediment to the emptying of the corresponding auricle. The auricular pressure is therefore raised, and this leads to a rise in pressure in the veins which drain into the affected auricle and to congestion in the vascular bed from which these veins arise. Since in most of the common types of heart disease the greater strain is on the left side of the heart, such congestion usually occurs first in the pulmonary circuit, where it produces the clinical manifestations of dyspnea, cough, rales in the lungs (when the congestion has become severe enough to cause edema of the lungs), decreased vital capacity and prolongation of the pulmonary circulation time. In most cases congestion in the systemic circuit does not occur until the increase in pulmonary pressure has become sufficiently great to induce secondary dilata-

tion of the right ventricle with a rise in the pressure in the right auricle. When this takes place the characteristic manifestations of systemic engorgement can be noted. These include distention of the veins, enlargement of the liver, edema of the lower portion of the body and albuminuria.

Some of the important features and causes of these two general types of heart failure are summarized in table 1. The discussion to follow will, however, be concerned solely with the diagnosis of backward (congestive) failure, because this is the common type of chronic heart failure.

Before a diagnosis of congestive heart failure can justifiably be made in a given case two questions must be answered in the affirmative. These are 1. Does this patient have heart disease? 2. Is congestive heart failure the only syndrome which can account for the symptoms? Since the answers to these two questions are based on entirely different criteria, they will be considered separately.

THE DIAGNOSIS OF HEART DISEASE

Attempts to discuss in detail the evaluation of all the various manifestations of heart disease would obviously lead too far afield. For the purpose at hand it will suffice to mention briefly some phenomena which are practically diagnostic of heart disease and other manifestations which are suggestive of it. A reliable history of substernal distress appearing during muscular effort and disappearing within a few minutes after the subject has begun to rest is almost certain evidence of angina pectoris and hence of a certain type of heart disease. The presence of enlargement of the heart constitutes conclusive evidence that heart disease is present. Diastolic murmurs almost invariably mean heart disease. (It is recognized that occasionally functional diastolic murmurs occur in persons with marked hypertension or even in persons with thyrotoxicosis or severe anemia. However, such murmurs are rarely if ever seen except when the process has involved the heart, and hence one is justified in regarding a diastolic murmur as constituting almost certain evidence of heart disease.)

There are certain other phenomena which constitute suggestive evidence of heart disease. These include a history of rheumatic fever, long-standing and well marked elevation of the blood pressure, chronic auricular fibrillation, a heart rate which is below 40 persistently, and gallop rhythm with the extra sound occurring in diastole. The latter phenomenon in itself is practically diagnostic of heart disease but is listed among the suggestive signs because occasionally it may be impossible to distinguish between a normal third heart sound, an audible auricular contraction, reduplication of one of the sounds and true gallop rhythm. Another sign which usually indicates the presence of heart disease is a persistent and very loud systolic murmur. (Faint or even moderately loud systolic murmurs are often heard in the absence of structural disease in the heart.) Finally, there are certain electrocardiographic manifestations which suggest the presence of heart disease. These include a well marked prolongation of the auriculoventricular time, bundle branch block, aborization block and certain deformities of the T waves and the ST intervals. Practically every patient with structural disease of the heart will be found on examination to present one or more of the manifestations that have been mentioned. Of them enlargement of the heart is the most common and the most important.

From the Department of Medicine, Vanderbilt University School of Medicine.

Read in the Medical Division of the General Scientific Meetings at the Ninety-First Annual Session of the American Medical Association, New York, June 11, 1940.

THE RECOGNITION OF CONGESTIVE HEART FAILURE

The symptoms and signs of congestive heart failure are listed in table 2. They fall into two groups according to whether the congestion is in the pulmonary circulation (left-sided failure) or in the systemic circulation (right-sided failure). The most important manifestation of failure of the left side of the heart is dyspnea, appearing either on slight exertion or—more typically—at rest. However, heart disease is not the only disorder which causes shortness of wind. This symptom when appearing on effort is commonly due to obesity, emphysema, bronchitis, bronchiectasis, anemia or almost any debilitating disease. However, in many instances dyspnea is accompanied by weakness and fatigability, and the patient's chief complaint is of the latter symptoms. It is only when there is heart disease, abnormality of the lungs or marked obesity that dyspnea is likely to occur with slight muscular effort in the absence of weakness and fatigue. Shortness of breath at rest may be due to a psychoneurotic state (which is commonly associated with sighing rather than with panting); it may be due to bronchial asthma, to abnormalities of the trachea or bronchi, to accumulations of fluid in the chest or to acute infection in the lungs. Most of these conditions can be readily differentiated from the dyspnea of heart disease by the presence or absence of the signs just mentioned which point toward heart disease.

Attacks of dyspnea, usually occurring at night, constitute one of the most important manifestations of failure of the left side of the heart. Such attacks are of two types: (a) cardiac asthma, which sets in after the subject has been soundly asleep and which has to be differentiated from seizures of dyspnea due to bronchial asthma or to rarer causes of respiratory obstruction, and (b) Cheyne-Stokes respiration, which usually appears just as the subject sinks into sleep. Periodic breathing may occur in patients with cerebral hemorrhage, pneumonia, uremia, advanced cerebral arteriosclerosis and the like. However, it rarely leads to severe subjective respiratory distress except when the patient has congestive failure.

TABLE 1.—The More Common Types of Heart Failure

Major Type	Chief Physiologic Disturbance	Subtypes	Comment
Forward failure	Inadequate tissue blood supply (especially to the brain)	Sudden death	Angina pectoris
		Cardiac syncope	Adams-Stokes disease
Backward (congestive failure)	Engorgement of vascular bed (pulmonary, systemic or both)	Cardiac collapse *	Acute myocardial injury
		Left-sided failure	Extreme tachycardia
		Right-sided failure	Mechanical hindrance
			Pulmonary congestion
			Systemic congestion

* The clinical picture is like that of surgical shock except for evidence of congestion—either pulmonary, systemic or both.

Since dyspnea is the most important clinical manifestation of failure of the left side of the heart, this symptom needs to be investigated carefully, not only by questioning the patient concerning his sensations but by observations of the breathing during and after exercise. The exercise selected should usually be one which is just severe enough to make a normal person slightly conscious of his breathing. If the physician will walk at a moderately rapid rate up two or three flights of stairs with the patient and compare his own

breathing with that of the patient, he will often obtain information which is a valuable supplement to the patient's statement with regard to his shortness of wind. This simple test is one of the most useful methods of examination of the heart, and it is even more important in persons with suspected angina pectoris than in patients with suspected heart failure.

TABLE 2.—The Important Clinical Manifestations of Congestive (Backward) Failure

I. Failure of left side of heart
Dyspnea
On exertion
Orthopnea
Cardiac asthma
Cheyne-Stokes respiration
Cough
Rales at lung bases
Diminished vital capacity
Prolonged pulmonary circulation time
Increased vascular shadows in lungs
II. Failure of right side of heart
Increased venous pressure and distended veins
Edema of dependent parts
Enlarged, tender liver
Cyanosis
Albuminuria
Prolonged peripheral circulation time

Coughing is a common symptom of failure of the left side of the heart. However, in this condition the dyspnea is usually predominant and the cough a secondary symptom. In bronchitis and many other diseases of the lungs the cough is more pronounced than the dyspnea. These rules admit of occasional exceptions, and one sometimes observes a troublesome cough—supposedly due to bronchitis—disappear completely following digitalization.

One of the errors commonly made in the diagnosis of heart failure is the assumption that the absence of rales in the lungs means that these organs are not congested. Actually, rales are a sign that the dyspnea has become severe enough to produce edema of the lungs, and in many cases a moderate degree of pulmonary congestion exists in the absence of rales.

Measurement of the vital capacity is a helpful procedure in the diagnosis of left-sided heart failure. In interpreting such measurements it should be remembered that normally the vital capacity is greater in men than in women, in the young than in the elderly, in thin persons than in fat persons, and that individuals who take considerable exercise usually have higher vital capacities than those who lead sedentary lives. It should likewise be borne in mind that many diseases other than those which affect the heart may reduce the vital capacity, common examples being emphysema and bronchiectasis. Because of these variables, a single measurement of the vital capacity is of relatively little value in the diagnosis of heart failure. However, repeated measurements are often quite helpful, especially when carried out before and after the use of therapeutic measures which have a beneficial effect in persons with congestive failure. A distinct rise in vital capacity following the administration of adequate doses of digitalis constitutes strong evidence that the decrease in vital capacity existing before the administration of the drug was the result of congestive heart failure. This simple procedure, coupled with an evaluation of the patient's statement with regard to the degree of dyspnea experienced on standardized effort before and after digitalis, constitutes one of the most helpful methods of diagnosing the mild degrees of pulmonary congestion in doubtful instances.

Among the other methods which are often of value in the diagnosis of failure of the left side of the heart are measurements of the pulmonary circulation time and study of the pulmonary vascular markings in the x-ray film.

The recognition of failure of the right side of the heart rarely presents difficulties if the failure is severe. The combination of marked edema of the lower part of the body, enlargement and tenderness of the liver in association with pronounced distention of the veins produces a characteristic picture. However, when these manifestations are quite mild, difficulties may arise. These difficulties can usually be overcome by attention to a few simple principles.

ence is not some arbitrary point on the chest wall but the posterior part of the vertebral column, which bears a fairly fixed relationship to the level of the auricle. The patient should lie on a flat table and the venous pressure should be measured as the vertical distance from this table to the point at which saline solution fails to descend into a needle in the antecubital vein. Measured in this way, the normal venous pressure is from 150 to 220 mm. of saline solution. Provided the subject has been at rest on the table for a number of minutes, is thoroughly relaxed, is not excited and is breathing quietly, a value of 250 mm. or more by this method represents an abnormally high venous pressure. However, such an elevation does not necessarily mean the

TABLE 3.—The Differential Diagnosis of Failure of the Left Side of the Heart

Condition	Signs of Heart Disease	Dyspnea			Cough	Sputum	Rales	Pulmonary Circulation Time
		Exertion	Orthopnea	Paroxysmal				
Failure of left side of heart	+	++	+	+	+	None, frothy (acute pulmonary edema) or blood (infarction)	Moist	Prolonged
Obesity	0	+	0	0	0	0	0	Normal
Anemia	Systolic murmur, loud sounds	+	0	0	0	0	0	Rapid
Bronchitis, bronchiectasis	None or slight enlargement of right ventricle	+	±	+	+++	Abundant or thick and tenacious	Dry	Normal
Lung tumors	0	+	0	±	++	"Raspberry juice" or none	None or unilateral	Normal
Pneumonia and other severe infections of lungs	0	++	0	0	+++	Rusty	Often unilateral or patchy	Normal

TABLE 4.—The Differential Diagnosis of Failure of the Right Side of the Heart

General Condition	Specific Condition	Elevation of Venous Pressure		Anasarca		Enlarged Liver	Cyanosis	Albuminuria	Signs of Heart Disease	Left-Sided Failure
		Cubital	Femoral	Edema	Ascites					
Failure of right side of heart	Any cause of heart disease	+	+	+	+	+	+	+	+	+
Caval obstruction	Superior	+	0	Arms	0	0	Face, neck and arms	0	0	0
	Inferior	0	+	Legs	± or 0	± or 0	Legs and abdomen	+	0	0
Hypoproteinemia	Nephrosis	0	0	++	++	0	0	+++	0	0
	Nutritional (protein deficiency)	0	0	+	+	0	0	0	0	0
	Liver disease	0	0	+	++	+	0	0	0	0
Portal obstruction	Cirrhosis, portal thrombosis, etc.	0	+	+	++	Large or small	Abdomen only	±	0	0
Chronic peritonitis	Tuberculosis, carcinoma	0	+	+	++	Absent to marked	0	±	0	0

In evaluating the appearance of the veins one must remember that it is not the volume of blood in the veins but the pressure within these channels which is of importance in indicating failure of the right side of the heart. The vertical distance above the heart level at which the cervical veins collapse is therefore of more importance than the actual size of the vessels. Under normal conditions the cervical veins collapse at a point about 10 cm. (or less) above the auricular level. If the veins are distended at a point more than 15 cm. above the auricular level it is probable that the venous pressure is abnormally high, and such is certainly the case if these vessels are well filled 20 cm. or more above the heart level. In doubtful instances one should not be satisfied with the results of inspection but should measure the venous pressure. It has recently been shown by Burwell and his associates that for the purpose of such measurements the best point of refer-

ence is not some arbitrary point on the chest wall but the posterior part of the vertebral column, which bears a fairly fixed relationship to the level of the auricle. The patient should lie on a flat table and the venous pressure should be measured as the vertical distance from this table to the point at which saline solution fails to descend into a needle in the antecubital vein. Measured in this way, the normal venous pressure is from 150 to 220 mm. of saline solution. Provided the subject has been at rest on the table for a number of minutes, is thoroughly relaxed, is not excited and is breathing quietly, a value of 250 mm. or more by this method represents an abnormally high venous pressure. However, such an elevation does not necessarily mean the

presence of congestive heart failure, as it may be brought about by various conditions which increase the intrathoracic pressure, by disorders—such as aneurysms and mediastinal tumors—which compress the superior vena cava and by thrombosis of this vessel. Aside from congestive heart failure, the most common causes of increase in venous pressure are conditions, such as bronchial asthma, which interfere with the deflation of the lungs and which therefore elevate the intrathoracic pressure.

Although congestive failure is probably the most common cause of a significant degree of edema, it is by no means the only cause. Deficiency of the serum proteins due to inadequate protein intake (nutritional edema), to excessive loss (nephrosis) or to inadequate formation (certain diseases of the liver) may likewise cause general edema. Such patients are usually not dyspneic and hence lie flat in bed; the edema tends to

be more evenly distributed than of patients with heart disease, in whom orthopnea forces the patient to assume a position (sitting) which causes the greatest venous pressure to be exerted in the legs and abdomen, with a relatively small venous pressure in the face. Hence the patient with heart disease ordinarily has no edema of the face in comparison to the striking edema of the lower part of the body. However, this general rule admits of occasional exceptions, for in certain types of heart disease (tricuspid stenosis, constrictive pericarditis) there is usually little or no pulmonary congestion and therefore, since dyspnea is minimal, the patient may lie flat in bed and hence have edema of the face as well as of the lower parts.

The enlarged liver of congestive heart failure has to be differentiated from all other conditions that cause a large smooth liver. Such differentiation usually needs to be based on a consideration of the associated phenomena rather than on the physical signs concerned with the liver itself. In patients with right-sided heart failure of short duration and of progressive nature the liver is usually tender. However, if the enlargement has persisted for a considerable time the tenderness usually disappears. Occasionally the pain due to sudden enlargement of the liver resulting from heart failure may lead to a mistaken diagnosis of gallbladder disease.

Although cyanosis is not a constant feature of congestive heart failure, it occurs to some degree in many cases. It may be brought about by arterial anoxia as the result of pulmonary edema or emphysema, by distention of the small veins in the skin as the result of the increased venous pressure or by diminished circulation through the skin, especially when the heart failure is of sudden onset. The presence of cyanosis is therefore a suggestive sign of heart failure when the patient has other manifestations pointing toward it. The absence of cyanosis does not signify the absence of heart failure.

In tables 3 and 4 a summary is presented of certain points which are useful in differentiating heart failure from some of the more common conditions which may simulate it. The tables are not in any sense comprehensive but include only those conditions which are frequently encountered and which are especially likely to lead to confusion.

SUMMARY

There are several different types of heart failure, the most important of these being congestive heart failure. The diagnosis of this condition depends on finding evidence of heart disease plus evidence of congestion either in the pulmonary or in the systemic circuit. The most common important signs of heart disease are enlargement of the heart, diastolic murmurs and gallop rhythm. The clinical manifestations of congestion in the pulmonary bed consist of dyspnea (including orthopnea and paroxysmal dyspnea), cough, rales at the lung bases, diminution in vital capacity, prolongation of the circulation time and the appearance of increased vascular markings in the x-ray film. Failure of the left side of the heart is the most common type of congestive heart failure and usually precedes failure of the right side, which leads to edema, increase in venous pressure with distention of the veins, enlargement of the liver, cyanosis and albuminuria. No single sign of congestive heart failure is specific, as all the manifestations may at times be produced by other conditions. Hence the diagnosis cannot be made on the finding of any single phenomenon but rather must depend on a consideration of the entire clinical picture.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE.—In their elaboration, these articles were submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, the late Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. When completed, the series will be published in book form.—Ed.

THE THERAPY OF BARBITURATE POISONING

IN COLLABORATION WITH DR. RICHARD KOHN RICHARDS
NORTH CHICAGO, ILL.

The patient who suffers from barbiturate poisoning usually arrives at the hospital in coma, with the reflexes and pupillary reactions retained or even exaggerated. The barbituric pupil is usually dilated with normal or slightly delayed pupillary reaction (and it is small and reactionless only in extreme cases); the pupil of morphine poisoning is generally small and becomes dilated only shortly before death. In case of barbiturate coma quite frequently a rhythmic widening and narrowing of the pupil (hippus) is observed. Presence of hippus makes the prognosis somewhat more favorable than if there is no reaction present.

A simple test for barbiturates in the urine which is approximately quantitative has been described by Koppányi, Murphy and Krop.¹

Newer tests which are more accurate and less time consuming than the isolation of the crystalline material have been developed. A method based on the color reaction with cobalt is described by Brundage and Gruber.² A good modification has been worked out by Delmonico.³

The fatal dose is, in general, from fifteen to thirty times the therapeutic dose. The dose of barbituric which is nearly always fatal is about 10 Gm., that of phenobarbital from 6 to 8 Gm. and that of dial about 2.4 Gm. The mortality rate may exceed 20 per cent. Symptoms of barbiturate poisoning generally continue for several days before death or recovery takes place.

When a patient is admitted to the hospital in the stage of coma, the following procedure should be carried out:

1. Evacuation of the stomach should be done, with the patient's head lower than the stomach (best carried out on the operating table to prevent aspiration of fluid overflowing from the stomach around the tube, with subsequent development of aspiration pneumonia). If trismus is present the duodenal tube should be passed through the nose. Lavage with Potassium Permanganate solution 1:5,000 may be useful against some barbiturates even when the poison has been taken many hours previously.

To clear unabsorbed poison from the bowel, sodium sulfate or sodium phosphate is preferable to magnesium sulfate, as reabsorption of magnesium during the coma might result in an increase of the depression and should be left in the stomach with Fluidextract of Cascara

Dr. Fantus died April 14, 1940.

3. Delmonico, E. J.: *Tests for Derivation of Barbituric Acid*, *Proc. Staff Meet., Mayo Clin.* 14: 109 (Feb. 15) 1939.

Sagrada (16 cc.). The tube should be left in place. If no bowel movement is secured, this should be followed in a few hours by 30 cc. of Castor Oil. Enemas may be required in addition, and these might well consist of hot strong black coffee, any quantity of which retained also serves as an antagonist.

2. Postural drainage should be maintained continuously. The foot end of the bed is elevated to tilt the bed from 15 to 20 degrees, the patient's feet being tied to the end of the bed if necessary and the patient's head turned to the side. Secretions accumulating in the pharynx should be removed by suction. Insertion of an airway to prevent falling back of the tongue is advisable in any deep coma in addition to periodic removal of accumulated secretion in the pharynx. If the patient is cyanotic, and many of them are, oxygen should be administered by a nasal catheter. If the respiration is shallow, the administration of a few whiffs of carbon dioxide every half hour improves respiration and has a general analeptic effect.

3. Feeding should be done through the stomach tube at intervals of every four hours, with two cups of not excessively hot strong coffee with some milk. When a feeding is due, the stomach should always be evacuated of its contents before injection of the feeding so as to avoid overdistention of the stomach and possible overflow around the tube and aspiration into the lungs. One might be somewhat hesitant about feeding a patient in deep coma by stomach tube, since the postural drainage position in the stage of deepest depression may lead to regurgitation. Oral feeding should not be started before the vegetative reflexes are reestablished. In the meantime, parenteral fluid administration, dextrose with saline solution, should be given with judgment. Particularly, the development of a pulmonary edema should warn against a careless or excessive administration of fluids. Intravenous injections of hypertonic solutions, i. e., 25 per cent dextrose, are often helpful. What frequently appears to be pulmonary edema after the patient is admitted are really rales of accumulated mucus, which disappear if the patient is properly nursed.

It is a peculiar observation that patients with severe barbiturate poisoning soon start to have a high temperature even if no pulmonary complications are demonstrable.

4. An important part of the therapy consists of liberal administration of analeptic drugs, i. e., stimulants which counteract the depressant action of the barbiturates on the central nervous system. At present it seems that sufficient evidence has been collected to warrant the recommendations of picrotoxin as the most powerful stimulant in all cases of severe barbiturate poisoning. The drug should be given in doses of from 6 to 12 mg. intravenously, depending on the degree of coma. It is used as a 0.3 per cent solution, each cubic centimeter containing 3 mg. An interval of fifteen minutes should pass between two injections in order to account for the latent period inherent in this drug. Improvement of respiration, slight movements and moaning are the first signs of favorable response. In cases of severe poisoning, large doses have been given even before a diminution of the anesthesia is noticed. Slight twitchings of the facial muscles are a sign that the optimum effect of the drug is about attained. Under no circumstances should one try to induce complete awakening, since this might lead to convulsions. The long acting barbiturates are harder to overcome than the short acting group. Picrotoxin treatment should not be started without

having a soluble-barbiturate such as, for instance, pentobarbital sodium, pentothal sodium or amytal readily available for intravenous injection in case severe convulsions develop. It is wise to stay sufficiently below the convulsion level and to be satisfied with improvement in respiration, restoration of the cough and swallowing reflex and production of spontaneous movements. All these factors start to prevent stasis and pulmonary complications which are the main danger in subacute barbiturate poisoning. If such a response has been produced, one may continue to give the drug at one half or one hour intervals intramuscularly. In case the coma deepens again, more frequent medication has to be resorted to.

Metrazol is a stimulant almost as powerful as picrotoxin but does not seem to be quite as prolonged in its action clinically. It has no latent period, and the maximum effect starts almost immediately after injection. Several cubic centimeters of the 10 per cent solution should be injected intravenously at intervals until the desired effect is reached. Afterward, intramuscular injection can be resorted to.

Nikethamide, which is a good respiratory stimulant, is definitely inferior to picrotoxin or metrazol as an analeptic in stages of severe barbiturate depression. Strychnine Nitrate 2 mg. hypodermically every hour or two has been given until there is increased reflex excitability and this procedure is still recommended by several authors. Since strychnine, however, has primarily a spinal reflex action, it seems inferior to either picrotoxin or metrazol. Caffeine with Sodium Benzoate is not a very strong stimulant but it can be given in repeated doses of 0.5 Gm. intramuscularly because of its favorable effect on diuresis and the heart muscle.

5. Elimination should be cautiously assisted by 5 per cent dextrose phlebotomy to maintain free secretion of urine, but development of pulmonary edema should be watched for. Diuresis may be helped by a xanthine diuretic, e. g. aminophylline (Theophylline with Ethylene Diamine) in doses of 0.25 Gm. in 10 cc. of water, which may be given in the dextrose infusion, possibly every eight hours. Catheterization should be done every four to ten hours.

6. The body temperature should be kept from falling below the normal level by the application of external heat with great care to prevent burns. In conditions of subnormal temperature, heat is the greatest of all stimulants. It is a requisite to permit medicinal stimulants to act properly, and it may prevent the lowering of resistance that favors the development of pneumonia.

7. Artificial respiration with inhalation of oxygen should be instituted on the appearance of marked enfeeblement of respirations. Death from primary paralysis of respiration is, however, very rare. Death from primary failure of circulation occurs only in cases in which the heart is diseased.

In a serious case in which the blood pressure not infrequently drops to 80 mm. systolic, energetic treatment of the circulation appears desirable. One may give these patients at once 0.25 mg. of strophanthin-K intravenously and repeat this dose at twelve to twenty-four hour intervals for the first day or two if necessary. Ephedrine is also useful in raising the blood pressure. The injection of 1 cc. of solution of pituitary has been very helpful in imminent pulmonary edema. It raises the blood pressure and tightens the capillaries.⁴ Digital-

4. Poulsson, L. T.: Ueber die exsudationshemmende Wirkung des Pituitrins, Arch. f. exper. Path. u. Pharmacol. 120: 120, 1927. Tainter, M. L.: Comparative Antiedemic Efficiency of Epinephrine and Related Amines and Pituitary in Experimental Edemas, J. Pharmacol. & Exper. Therap. 33: 129 (June) 1928.

ization should, if possible, precede the solution of posterior pituitary in order to insure sufficient reserve power for the heart to overcome the increased resistance. It is advisable in cases of deep coma to make a spinal puncture and to determine the spinal pressure. The pressure should be reduced in case it is elevated, since cerebral edema is one of the most serious complications of barbiturate poisoning. Intravenous injection of sucrose or, better, sorbitol, reduces intracranial pressure.

STAGE OF REACTION

Usually by the end of the first day the temperature rises, respiration becomes embarrassed, foci of pulmonary edema, congestion or consolidation develop, the blood pressure falls and the pulse becomes enfeebled. The pulmonary sequelae are probably in most instances the result of the general vasoparesis with or without subsequent infection. Nevertheless, everything should be done to prevent the possibility of a suspicion that they are due to aspiration or to chilling. The treatment is that of pneumonia (q. v.).

Great tendency to decubitus (q. v.), also due to vascular paresis, requires special precautionary measures.

Constant nursing care is imperative to give these desperately sick and helpless patients their best chance for survival.

Special Article

CONFERENCES ON THERAPY

MANAGEMENT OF DIABETIC EMERGENCIES:

II. TREATMENT OF SURGICAL PATIENTS AND CHILDREN

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.

DR. EUGENE F. DU BOIS: We are going to continue the discussion of diabetes with a contribution from Dr. Conway, who will discuss the surgical aspects.

SURGICAL ASPECTS OF DIABETES

DR. HERBERT CONWAY: In planning a surgical procedure for the diabetic patient, the exact state of the diabetes must be taken into consideration as a basis for the management of the preoperative treatment, the selection of the anesthetic and the type of operation. The diabetic patient, even though his disease is under medical control, must undergo greater surgical hazard than the nondiabetic person. There is a factor, which may be referred to as x , which operates against the welfare of the diabetic subject. It manifests itself in many ways. Wounds heal slowly. Tissues are non-resistant to infection. Pus dissects easily along fascial planes. Micro-organisms cause gangrenous sloughs in the tissues. Postoperative mortality rates for these patients are higher than for the nondiabetic. Surgery of the gallbladder, which is attended with an operative mortality of from 1 to 2 per cent, carries a mortality rate of from 6 to 7 per cent among the diabetic. Acute appendicitis shows greater virulence. Carbuncles, always serious, not uncommonly result fatally in the early postoperative period.

Gangrene of an extremity in association with diabetes is probably the most important complication with which

the surgeon deals in the diabetic patient. Of a total of 1,333 patients admitted to the New York Hospital as diabetic during the past seven years, fifty-six, or 4.2 per cent, had gangrene of an extremity. In nineteen of these cases mid thigh amputation was performed with nine deaths, a mortality of 47.4 per cent. In the same period (1932-1939) twenty-six patients who had arteriosclerotic gangrene with infection were subjected to mid thigh amputation with only four deaths, a mortality of 15.3 per cent. The level of amputation for diabetic gangrene is determined after consideration of the extent of the infection, the state of the patient and the efficiency of the circulation. There are no completely satisfactory tests by which the ideal level for amputation can be determined. The saline wheal test (Stern), the histamine test (de Takats), nerve block (Morton and Scott), arteriography and the tourniquet test (Brooks) have not been found to be wholly reliable guides. There are, however, certain general rules which guide the surgeon. It is believed that simple amputation of the toe will be successful if the dorsalis pedis pulse is present, if there has been little pain and if the infection has not spread over the dorsum of the foot. Amputations through the foot have not been advised for the diabetic because the efficiency of the circulation at this level is not ideal. Amputations below the knee are not done unless there is evidence that the patient is of the type who can accept a prosthesis. Amputation should not be done below the knee if a pulsation cannot be palpated in the popliteal artery. Amputation through the knee joint (Gritti-Stokes) is not recommended for diabetic patients because the success of the amputation depends on the use of a flap of soft tissue in the region of the patella, a circulatory burden which is too great for the extremity of a diabetic person. In cases in which simple amputation of the toe is not successful, it has been necessary commonly to resort to the circular mid thigh amputation.

DR. DU BOIS: There is nothing more important for the medical man than a knowledge of what surgery can offer in diabetes, and judgment is extremely difficult.

DR. EPHRAIM SHORR: I think it is of considerable importance for medical men to know what to do, if possible, about the prevention of surgical complications, and also what conservative measures are likely to prove of help.

DR. CONWAY: Conservative treatment consists in the application of dressings which should be dry. We usually put the patient in bed, with the leg at the level of the heart so that the circulation may be maintained with minimum difficulty. A cradle with electric lamps increases the vasodilatation, and moist dressings are avoided because they may activate the infection and convert what might have been dry gangrene into wet gangrene. We believe that forcing of fluids is essential in order to dilute the circulating stream of blood and diminish its viscosity. If there is no infection, the leg can be put into a glass boot in which alternate suction and pressure are applied. That is, we believe, a helpful method of arresting the advance of gangrene. But if infection is present, that device should not be used because it may promote the extension of the infection along the lymphatic channels. Minor incisions to drain accumulations of pus, or excision of an area of slough, may be necessary.

DR. SHORR: What about preventive measures? What do you tell diabetic patients, for instance, about their shoes, the care of their feet, the selection of their socks and so on?

DR. CONWAY: Most of this preventive work is carried out before they come under our observation. All of our nineteen patients who were subjected to mid-thigh amputation were admitted to the hospital in a state of emergency and had not had previous care. We believe, as Dr. Shorr does, that the condition is probably preventable. Care of toe nails is tremendously important. Ingrown toe nails should not be allowed to develop. The patients should be taught to cut their nails transversely and to pack cotton under them to prevent their growing into the epithelial surface. They are cautioned about injuring their legs, about the danger of cutting them, about being around gymnasiums or places where they might contract athlete's foot. If they contract athlete's foot, they are immediately put under treatment to prevent abrasion of the skin, which might provide a port of entry for infection. Frequently we advise shoes a size larger than they would ordinarily need, being careful that the foot does not rub in the shoe. We often advise heavy woolen socks to keep the lower extremities warm and promote vasodilatation. Some clinicians recommend a soft rabbit's fur lining for a specially made shoe. The other measures are the ones which are instituted in arteriosclerosis generally, involving exercises of the Buerger-Allen type, in which the patient puts his legs and feet through regular motions. Inunctions of the skin with hydrous wool fat, cottonseed oil or theobroma oil are of value in softening the skin and preventing the shiny tight surface which promotes abrasions.

DR. HARRY GOLD: How has insulin therapy changed the mortality in the class of patients discussed?

DR. CONWAY: All of our patients are managed in this institution by the combined efforts of the medical consultants and ourselves, and insulin therapy is instituted from the outset. The older surgical records show that this condition was usually fatal before the advent of insulin.

DR. DU BOIS: Dr. Tolstoi, have you seen gangrene develop in patients under what would be considered good control?

DR. EDWARD TOLSTOI: I have. I was going to ask Dr. Conway whether there is such an entity as "diabetic" gangrene, whether the entire process is not vascular, because we do not see it in young people at all even in severe diabetes. In young patients who are severely diabetic this particular lesion is conspicuously absent. From my observations two types of diabetic persons are prone to this complication: One is the individual in the fourth to the fifth decade who has arteriolar disease. The small vessels are involved. In this type of infection wet gangrene commonly occurs. There is no occlusion of a major vessel causing the extremity to shrivel and dry up. In the older group in the sixth to the eighth decade the major vascular accidents occur and with them dry gangrene. All these gangrenous lesions are associated with vascular disease and not so much with the diabetes.

DR. GOLD: Isn't it a fact, however, that vascular degeneration develops in the presence of diabetes rather rapidly and to a degree that is out of all proportion to that seen in similar groups without diabetes? In that sense wouldn't the term diabetic gangrene apply?

DR. TOLSTOI: We have limited our study to younger diabetic groups, taking roentgenograms of their leg vessels and studying their blood cholesterol. We have used all the criteria proposed by the group who postulate that diabetes disposes to arteriosclerosis. We have

watched these severely diabetic groups now for a period of seven years, taking x-ray plates at intervals of six months, and we have been unable to note any calcific lesions in their vessels. On the other hand, I recall a diabetic woman 22 years of age whose symptoms were only two months old as far as we could ascertain, and the roentgenograms of her tibial vessels showed marked calcific deposits. With such facts it is difficult for me to accept the postulate that diabetes predisposes to vascular sclerosis. That view may have been tenable in the preinsulin era, but it certainly should be challenged today, to stimulate further studies in that direction. I wonder whether the study of a large control group under 40 might not lead to a reconsideration of the existing hypotheses. Enklewitz, of the Montefiore Hospital in this city, studied this question about five years ago. He questioned the role played by diabetes in the causation of atherosclerosis.

I would prefer to call the condition gangrene in the diabetic rather than diabetic gangrene. It may appear academic, but I do think there is a pathologic distinction.

DR. DU BOIS: I was particularly interested in this so-called α factor that Dr. Conway emphasized. I think it is real. Every one knows that diabetic patients do badly, but what is this factor? I don't quite believe it is high blood sugar, tissue damage or faulty metabolism. Does it persist after the diabetes has been under control? If a man has been severely diabetic and is brought under adequate control for six months or so, is that so-called α factor still present?

DR. CONWAY: I recall one case in which I thought the α factor had vanished because the patient went through primary healing after a surgical operation, but I believe it is present to some extent even after adequate control. I do not think that insulin therapy corrects everything in the diabetic patient as far as major trauma or surgical operation is concerned.

DR. DU BOIS: Can we get some dissenting opinion on that?

DR. TOLSTOI: I should like to voice a contrary opinion. I believe that the view that healing is delayed in the diabetic is a carry-over from the old régime. Dehydration was outstanding at that time. If the diabetic patient is hydrated and no infection sets in, healing will take place. Dr. Conway was good enough to do one or two surgical amputations for us on patients well hydrated and he expressed surprise at the satisfactory healing of the wound, though the patients were quite old. Sufficient fluid is the deciding factor.

DR. SHORR: I should like to suggest infection as probably the major difference between those showing an adequate response and those showing no response to treatment. Once infection has entered the picture, it has been our general experience that treatment of the diabetes is much less successful.

TREATMENT OF DIABETES IN CHILDHOOD

DR. DU BOIS: Dr. Harrison, will you discuss the special problems in connection with children?

DR. HAROLD E. HARRISON: The principles for the treatment of diabetes in childhood do not differ from those in adult life, but there are certain idiosyncrasies found in the younger age group which are worth mentioning. One factor is the greater incidence of diabetic acidosis among children. Diabetic children may come into the hospital three or four times a year with diabetic acidosis even though they have been apparently competently handled on the outside and seem to have been

doing fairly well in all respects. A minor infection, a dietary indiscretion or some apparently unknown factor may precipitate diabetic acidosis. Children are also more susceptible to hypoglycemic shock than adults. Frequent mild insulin reactions may occur if an attempt is made to regulate the diabetes so that the urine is practically free from dextrose.

The onset of diabetic acidosis may be sudden. Usually among the first symptoms of importance are nausea and vomiting, always a danger sign in the child. A mistake commonly made is the interruption of the administration of insulin as soon as the child stops eating or becomes nauseated and vomits, in the belief that it is dangerous to give insulin unless the child can take food. As a result the acidosis progresses and becomes more severe than would have been the case if insulin had been continued and given in small repeated doses, the urine being examined for dextrose to avoid overdosage and hypoglycemic shock. Children with diabetic acidosis may become extremely dehydrated. The dehydration is in part due to loss of water and electrolytes in the urine during the diuresis associated with glycosuria, and in part to vomiting. When a diabetic child begins to vomit it is frequently impossible to give fluids by mouth until the diabetic acidosis is under control. Fluids by mouth merely aggravate the vomiting. It is therefore advisable to stop all administration by mouth and to give all fluids parenterally. Because of the severe dehydration which occurs, the administration of adequate amounts of saline solution is important. In a rather large series of children with diabetic acidosis Hartmann found that the plasma volume of some patients was reduced to almost half of the normal value. This indicates an extreme state of dehydration. The use of insulin and dextrose has already been discussed adequately by Dr. Tolstoi, and their use in the diabetic child is the same as in the adult except that the dosage is regulated according to the size of the child and the severity of the diabetes.

It is commonly said that circulatory failure in the child does not occur as often as in the adult, who may have vascular disease as well as diabetes. Nevertheless, with marked dehydration circulatory failure may occur as a result of the depletion of the plasma volume. Large amounts of salt and dextrose solution given to an extremely dehydrated child with circulatory failure often fail to raise the blood pressure permanently. In those patients the use of blood transfusions may be a life-saving measure. If blood transfusions are not given promptly, the blood pressure may abruptly drop further, and then no treatment may be of any avail. Death usually occurs in children with diabetic acidosis as the result of circulatory collapse. Even severe acidosis should not often cause death, if the diabetic child is properly treated. Joslin reported seventy cases of diabetic acidosis in children with but one death. Hartmann reported a series of ninety cases of diabetic acidosis in childhood with five deaths. Most clinics have had similar experiences with children with diabetic acidosis properly handled. Nevertheless, many deaths do occur and could probably be avoided by the use of modern methods of therapy.

Finally, something should be said about the use of alkali in the treatment of diabetic acidosis. Ordinarily it is not necessary to use alkali. If adequate amounts of saline solution are given, if renal function is normal and if the circulation can be maintained, readjustments of the serum electrolyte picture will take place without the use of alkali. However, in cases of severe acidosis

or when renal insufficiency is present, as it may well be in children with marked diabetic acidosis, administration of alkali restores the serum electrolytes to normal more rapidly than saline solution alone.

Hartmann has advocated the use of sodium lactate. He considers it preferable to sodium bicarbonate for two reasons: The sodium lactate is a more convenient solution to give parenterally. Secondly, it is only slowly converted into sodium bicarbonate, and he believes that there is no danger of alkalosis of any clinical importance through the use of sodium lactate. Darrow has used a solution of sodium chloride and sodium bicarbonate which can be given intravenously when required, and a mixture of this sort seems logical. However, these are refinements of technic. In most cases that one encounters they are not necessary if ample amounts of sodium chloride and dextrose solution or transfusions are given. The danger, of course, of the excessive use of sodium bicarbonate is that as the ketone bodies are oxidized there is an excess of base in the body and finally alkalosis may result. This can be avoided by a careful study of the patient and by the use of alkali in only moderate amounts.

STUDENT: In the adult it is customary to count on 2 Gm. of dextrose being oxidized by each unit of insulin. Is that ratio used to calculate insulin doses for children?

DR. HARRISON: That same ratio can be used for children. However, the value is a gross approximation only, and after the diabetic acidosis begins to improve 1 unit of insulin may oxidize much more than 2 Gm. of dextrose. If one were to use that value all along one might produce hypoglycemic reactions in the child. As the diabetic acidosis subsides the insulin apparently becomes more effective, and therefore much more carbohydrate should be given to cover the insulin dosage.

STUDENT: Are the reactions of the child more labile?

DR. HARRISON: Yes. The child is apt to have hypoglycemic reactions more readily than the adult, and the blood sugar may fluctuate more widely.

DR. DU BOIS: During infection or in diabetic coma how many units do you have to give to secure the oxidation of 1 Gm. of dextrose?

DR. HARRISON: That cannot be answered with precision. It is our experience that 100 units of insulin may sometimes be given without any apparent effect on the blood sugar for many hours.

DR. DU BOIS: Does that apply also to adults?

DR. TOLSTOI: Yes.

DR. CONWAY: How often do you see a death from diabetic coma in a child?

DR. HARRISON: In the large series that Hartmann reported the mortality rate was 5 per cent, and he felt that that rate could be lowered with his present methods of therapy. His series included patients observed during the past eight years.

DR. CONWAY: Does that apply here?

DR. HARRISON: I don't believe we have had any such deaths in this hospital during the past seven years.

DR. SHORR: Does the greater lability of the child's blood sugar level make the use of protamine zinc insulin more hazardous than in the adult?

DR. HARRISON: I don't think so, although it did seem at first that with protamine zinc insulin we observed extreme hypoglycemic reactions. Patients were found in comatose states in the morning, and it was very difficult to get them out of shock. However, now that

we do not attempt to get the urine free from dextrose, protamine zinc insulin can be used for children without any great hazards.

DR. SHORR: Proving helpful?

DR. HARRISON: Proving helpful in the elimination of multiple doses of insulin. It is more convenient in handling the diabetic child.

DR. ADE T. MILHORAT: Do you use gastric lavage for children who are vomiting and nauseated?

DR. HARRISON: It is an old pediatric custom to use gastric lavage when there is repeated vomiting, probably on the theory that in these children the stomach is dilated and filled with accumulated products which may irritate the mucosa and that their removal may help to allay the nausea and vomiting. Gastric lavage is done in such cases, and sometimes the children seem to stop vomiting immediately afterward. However, most of the time we discontinue fluids by mouth and do not resort to gastric lavage.

DR. VINCENT DU VIGNEAUD: How many cases were treated in Hartmann's series?

DR. HARRISON: Ninety cases.

DR. DU VIGNEAUD: With what mortality?

DR. HARRISON: There were five deaths in that series.

DR. DU VIGNEAUD: Was that broken down into the types of death? Were the patients all actually in acidosis?

DR. HARRISON: They all had severe acidosis. Two of the deaths were thought to be due to pneumonia, but the other three were apparently due to acidosis unsuccessfully treated.

DR. DU VIGNEAUD: I was wondering whether the patients died in acidosis or alkalosis?

DR. HARRISON: None of Hartmann's patients died in alkalosis.

DR. DU VIGNEAUD: We have heard much about the dangers of sodium bicarbonate therapy as compared with sodium chloride therapy, and I was wondering just how real this danger of alkalosis from sodium bicarbonate is.

DR. HARRISON: It is perhaps exaggerated. A chemical alkalosis may be produced in the sense that the plasma bicarbonate may be raised above normal, but clinically there may be no symptoms.

DR. DU BOIS: As to the various therapeutic agents that are mentioned as dangerous, such as insulin, protamine zinc insulin and bicarbonate, isn't it true that they are really quite safe when used intelligently?

DR. GOLD: Dr. Tolstoi regards a properly controlled diabetic patient as one who has no symptoms, who maintains an adequate body weight and who does not show acetone in the urine, although there may be a high blood sugar and the patient may be spilling a good deal of sugar in the urine.

According to the view presented by Dr. Shorr, diabetes represents an endocrine imbalance. The hyperglycemia and glycosuria are some of the indications of its presence. Even though they are in themselves not injurious, they nevertheless do reveal a state of metabolic imbalance which may involve injurious factors as yet unknown. In the present state of our ignorance, therefore, would it not be wiser to attempt to restore the balance even to the point of a normal blood sugar where feasible, in the hope of correcting possible disturbances in the metabolism of the diabetic which are

not revealed by present methods? That would not be necessary, of course, if we were quite certain that progressive deterioration was not going on even while body weight was maintained and the patient was free from symptoms and acetone in the urine. But are we quite sure? I recall that we had arrived at no positive decision regarding the question raised by Dr. Du Bois as to whether the x factor persists in the so-called adequately controlled patient.

By way of illustration, if a patient is discovered to have diabetes with hyperglycemia and glycosuria, quite accidentally, as in a routine examination, and if he qualifies under Dr. Tolstoi's criteria for the well controlled diabetic patient, should one proceed to treat him only by repeated examinations to discover any change in his condition that might take place or should one do something more about it? I think that at the present time most doctors would proceed to give him some sort of diet and insulin if necessary, sufficient to control the glycosuria as far as possible.

DR. TOLSTOI: I would treat the patient as having mild diabetes. My final decision would, of course, be determined by what I learned about the patient after a period of observation. However, at the beginning I would suggest that he be given one dose of 20 units of protamine zinc insulin and put him on a liberal diet. Although he may not need the insulin at present, it would afford him some protection, since long experience has shown that the untreated diabetic patient tends to progress to ketosis and coma. Having afforded him this protection with protamine zinc insulin, I would be little concerned about the level of his blood sugar and the extent of his glycosuria.

DR. SHORR: We know little about what the possibilities in diabetes are; the cautious treatment recommended by Dr. Tolstoi is the safer one at present.

SUMMARY

DR. DU BOIS: Would you be willing to bring together the points outstanding in this conference, Dr. Gold?

DR. GOLD: We have considered today first the special problems of surgery in the diabetic. The experience here at New York Hospital illustrates the well known susceptibility of the diabetic to infections and the danger of infection when it occurs in such patients. The proper surgical procedure in gangrene of the extremity is a matter of skilled surgical judgment to which few fixed rules can be applied. We have also had an account of the application of some of the more conservative measures both during gangrene and for prophylaxis.

Insulin has reduced considerably the mortality of these patients, although its use has not altogether eliminated the complications. It is interesting to note that the role of diabetes in the causation of vascular degeneration, a matter which has been quite generally accepted, is now being subjected to new scrutiny and doubt. Adequate control of the diabetic as we now know it still seems to leave them deficient and less able to meet the situation in infection and surgery, although dehydration may be the chief cause of the trouble and these patients may encounter no difficulty if abundant fluids are administered.

In diabetes in children, greater difficulties seem to exist in the maintenance of a balanced state. Acidosis is more frequent. Again, the use of abundant fluids with sugar and salt is the most important measure. Alkalis, while not essential, restore serum reticulocytes more rapidly than saline solution alone.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT.

PAUL NICHOLAS LEECH, Secretary.

PRESENT STATUS OF INJECTION TREATMENT OF HERNIA

In September 1936 the Council on Pharmacy and Chemistry¹ published a report on the injection treatment of hernia based on the replies to a questionnaire which had been addressed to a selected list of hospitals throughout the country. The questionnaire sought information particularly as to the extent of this practice, its safety and effectiveness, the incidence of unfavorable complications, and the nature of such complications. After consideration of the replies the Council concluded that, although there are cases in which this treatment is applicable and effective, nevertheless it should be borne in mind that the attempted cure of hernia by the application of the method of adhesive inflammation is not new; that it had failed to establish itself as a routine method for such treatment and was still in an early experimental stage; further, that physicians who practiced this method should realize the dangers from an ethical, a legal and a financial point of view.

To keep the Council's information up to date on this subject, the same questionnaire was again addressed to those hospitals which formerly replied. The questionnaire appears at the end of this report.

In reply to the inquiry whether or not the injection method is practiced, affirmative replies have been received from the same hospitals² which formerly stated that they used the method, except for one hospital which has now abandoned the method. The number of hospitals stating that they do not use the method remains the same as in the first tabulation; more hospitals seem to think the method is safe than unsafe, and more consider it ineffective than effective: in most cases the reply has been "effective only in selected cases." This would seem to agree with the consensus of the former report. In the 1936 report, it was stated:

Replies, which were received from most of the institutions addressed, indicated that the method is not used in the majority of the hospitals consulted and that it is considered safe and effective by those using it, although many qualified their opinion as to safety and effectiveness by specifying careful selection of cases. Several unfavorable complications were recorded, including mild infections, the development of fibrous masses of cutaneous tissue, and failure of the method to correct the hernia. In addition, there were some instances of painful scarring, occasional cases of swelling of the testis, and a few instances of subsequent impotence. In two cases, gangrene followed the use of the method.

Replies to the second questionnaire include reports of induration of the spermatic cord, atrophy of the testicle, numbness of the leg, edema of the leg, severe pain at times, slight symptoms of shock, localized peritonitis, impotence and recurrence of hernia. One hospital also reports the observation of a number of complications which resulted from the use of too strong solutions and the use of proper solutions in too great quantities. This hospital also reports the observation of several sloughs resulting from the solution's being injected into the subcutaneous fat instead of beneath the fascia.

As before, several hospitals report surgical operations on some patients who had been formerly treated by the injection method.

The solutions recently reported as being used include a mixture of oil of thuja, phenol and alcohol; sodium linoleate, sodium psylliate; tannic acid, and preparations of a proprietary character.

As indicated in the previous report, opinions vary as to the number of cases treated by this method in comparison to those treated surgically, but most of the hospitals now using the method report a rather low percentage of cases in which injections are given, such as "one injection to twenty surgical," "less than 50 per cent"; "5 to 10 per cent of those operated"; "8-10 per cent of cases subjected to this form of treatment"; "estimate it one to thirty-five"; "about 90 per cent [injection]"; "ten surgical to one injection." One hospital reports

that the "majority of cases presenting suitable indication (indirect inguinal hernia with small defect) are treated by injection method."

The consensus expressed by comments in reply to the last question indicate that one hospital has abandoned the injection treatment of hernia since the first questionnaire was reported, and others have narrowed its application to a smaller number of cases. Many hospitals concur in the opinion that this method is suitable only for small reducible indirect inguinal hernias. In general the importance of using careful technic, relatively nonirritating solutions and adequate truss support is indicated. Other hospitals indicate that surgical repair is the method of choice, the injection treatment being reserved for those cases suited to this method in which patients could not or would not undergo surgical operation. In some instances evaluation of the injection method is withheld because of inadequate follow-up or insufficient lapse of time. Cooperation of the patient in the matter of truss wearing is considered an important factor in success. In those hospitals not employing the injection method for hernia (about 65 per cent of those consulted) various reasons are given: Its original use has fallen into disrepute over a period of years and abandonment of its employment as a regular procedure is evidence that the method has no permanent value; it was previously abandoned because it failed to give useful results; scar tissue, whatever the origin, is a weak tissue, non-resistant to tension; the method is unestablished and opens the field of hernia treatment to incompetents, and the method is considered unsafe or unsatisfactory.

A review of the literature² since publication of the last report reveals that the weight of evidence is preponderantly in favor of acceptance of the injection method of treatment of hernia in carefully selected cases. In general most observers agree that

1. Injection Treatment of Hernia, *J. A. M. A.* **107**: 1053 (Sept. 26) 1936.

the injection treatment should not supplant surgery and, except in certain cases, does not offer as favorable a permanent result as the latter. Attempts to evaluate the two methods of treatment are frustrated by the lack of adequate follow-up records, with the additional difficulty that injection treatment has not been in use for sufficient time to permit accurate comparison. This is most frequently given as the explanation for a high percentage of cures with the injection method as compared to surgery. Percentages of failures or recurrences are unsuited for comparison for the same reason. Another difficulty is the matter of clinical decision whether or not recurrent bulging or impulse at the hernial site is evidence of insufficient number of injections or true failure of the method. The necessity for adequate follow-up is emphasized by many advocates of the injection treatment. Adherents of the surgical method point out that comparison of only eight to ten years' experience in the injection method with the much longer experience in surgical treatment is illogical and inconclusive.

Most observers indicate belief that the percentage of failures with the injection method will increase as adequate follow-up studies are reported. The majority state that they have observed no serious complications from hernias treated by the injection method and are generally agreed that relatively nonirritating solutions in skilled hands may be employed for certain cases with less potential danger than that of surgery. The criteria for safe and successful use of the injection method are given by various observers as follows:

1. Selection of Cases. Thin, young adults with good musculature. (Obese or aged individuals with atonic or atrophic supporting tissues are not suitable.)
2. Type of Hernia. Recent, small, reducible, indirect inguinal hernia with external inguinal ring not over 3 cm. in diameter. (Scrotal, direct inguinal, femoral, umbilical, ventral and incisional hernias are unsuitable. Sliding hernia associated with undescended testis and incarcerated hernias are contraindications.)
3. Truss Fitting. Skilled, adequate truss-maintained reduction before, between and after injections. (Incompletely or inadequately maintained reduction may occur with improper fitting or uncooperative patients.)
4. Injection Technic. Knowledge of inguinal anatomy and skill during injection are fundamental. (Surgical asepsis is, of course, imperative.)
5. Choice of Solution. Sterile, nontoxic fibrous tissue-stimulating, non-irritating solution is ideal. The fatty acid (soap) solutions approach nearest to these criteria. (Powerful sclerosing solutions are to be avoided and are believed responsible for many complications.)
6. Follow-Up. Repeated examination for periods of from six months to three years is necessary to determine length of treatment and period of truss wearing required for cure. (Inadequate treatment and truss support blamed for failures.)

After due consideration of the second hospital survey and the reports in the recent literature, the Council voted to adopt this report to reaffirm its previous opinion that the injection method of treating hernia may not be recognized for general use and should be employed only by those with special experience and with full cognizance of the dangers involved in the use of such solutions. The Council now concurs in the opinion that the method involves less danger of serious complications than surgery when employed only in selected cases of hernia by those skilled in the injection of suitable standardized solutions of known composition and action. The Council is not, however, willing to recognize any such solutions for New and Nonofficial Remedies until sufficient follow-up experience in their application has been gained to establish the success of the injection method of treatment. Present evidence indicates that better types of solution are to be desired.

In addition to the complications noted from the hospital surveys, the literature reveals case reports of death following perforation of the bowel from accidental intraperitoneal introduction of the needle, intestinal obstruction due to adhesions from inadvertent intraperitoneal injection or strangulation from failure to maintain reduction, perirectal abscess, fecal fistula and thrombosis of deep epigastric, iliac or femoral vessels. Most observers indicate that all serious complications can be avoided by skilful technic. The Council agrees and believes, therefore, that universal employment of the method is to be deplored. For this reason it is necessary that the Council condemn the exploitation of the injection treatment of hernia by manufacturers of solutions.

QUESTIONNAIRE

1. Is the injection method of treatment in hernia practiced in your hospital?
2. Do you consider the method safe and effective?
3. Have there been any cases of unfavorable complications?
4. What have been the nature of the complications?

5. Have you noted cases of impotence resulting from the injection method of treating hernia?
6. Have you records of gangrene or abscess formation following the use of the injection treatment?
7. If your staff feels the method is of value, what is the composition of the solution which it uses?
8. Do you know of any records of postmortem examinations indicating that death was due to the use of the injection method?
9. What is the ratio of the number of cases of hernia treated by the injection method in comparison to those treated surgically?
10. Any other comments?

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS FORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ASCORBIC ACID (See New and Nonofficial Remedies, 1940, p. 530).

The following dosage form has been accepted:

McKesson's Ascorbic Acid Tablets, 25 mg.: Each tablet contains 25 mg. of ascorbic acid-N. N. R., equivalent to 500 international units of vitamin C.

Prepared by McKesson & Robbins, Inc., Bridgeport, Conn.

OLD TUBERCULIN (See New and Nonofficial Remedies, 1940, p. 473).

Lederle Laboratories, Inc., Pearl River, N. Y.

Tuberculin Patch Test (Vollmer).—Prepared by the method of Vollmer under U. S. patent 2,190,745 (Feb. 20, 1940; expires 1957). Filter paper squares, 10 by 10 mm., are saturated with concentrated Old Tuberculin prepared by growing tubercle bacilli on the synthetic medium recommended by the Bureau of Animal Industry. These squares are dried and placed on strips of waterproof adhesive, 1 by 3 mm. in size, together with a control square made by saturating filter paper with concentrated uninoculated broth of the same composition which is used for producing tuberculin. The assembled adhesive strips are placed in moisture proof cellophane envelopes and sealed by heat. Marketed in packages each containing one complete test with control.

AMINOPHYLLINE-SEARLE (See New and Nonofficial Remedies, 1940, p. 557).

The following additional dosage forms have been accepted:

Tablets Aminophylline-Searle, 0.2 Gm. (3 grains).
Tablets Aminophylline-Searle, 0.2 Gm. (3 grains), Enteric Coated: The enteric coating consists of a mixture of mastic and magnesium stearate.

THIAMIN CHLORIDE (See New and Nonofficial Remedies, 1940, p. 528).

Thiamin Chloride-Squibb (See New and Nonofficial Remedies, 1940, p. 530).

The following additional dosage forms have been accepted:

Tablets Thiamin Chloride-Squibb, 3 mg.
Ampule Solution Thiamin Chloride-Squibb, 5 cc., 10 mg. per cc. 8-hydroxyquinoline sulfate 0.0025 per cent is used as preservative.
Ampule Solution Thiamin Chloride-Squibb, 5 cc., 25 mg. per cc. 8-hydroxyquinoline sulfate 0.0025 per cent is used as preservative.
Ampule Solution Thiamin Chloride-Squibb, 5 cc., 50 mg. per cc. 8-hydroxyquinoline sulfate 0.0025 per cent is used as preservative.
Ampule Solution Thiamin Chloride-Squibb, 10 cc., 10 mg. per cc. 8-hydroxyquinoline sulfate 0.0025 per cent is used as preservative.

The 8-hydroxyquinoline sulfate content of the foregoing solutions is determined as follows:

Add 0.1 cc. of ferric chloride test solution to 2 cc. of solution of thiamin chloride to be tested quantitatively for 8-hydroxyquinoline sulfate. Either dilute to 10 cc. or compare the color directly with a standard solution containing approximately 10 mg. of crystalline thiamin chloride and a known amount of 8-hydroxyquinoline sulfate (approximately 0.0025 Gm.) in 100 cc. of distilled water. The color is a bluish yellow green and group-characteristic for 8-hydroxyquinoline sulfate. It develops full intensity within two minutes and starts to fade after a period of six hours. The method is applicable to colorimetric analysis with an instrument, provided the concentrations are not too high. Thiamin chloride did not affect the determinations. The color development, however, depends on the hydrogen ion concentration. A μ of 3.0 to 5.0 is a favorable range.

The 8-hydroxyquinoline sulfate used as a preservative in Squibb's thiamin chloride solution conforms to the following standards:

8-hydroxyquinoline sulfate is a light yellow, crystalline substance, possessing a burning taste and characteristic saffron-like odor. It is easily soluble in water, dissolves with difficulty in alcohol and is insoluble in ether. The aqueous solution is acid to litmus. The melting point of the product is between 175-177 C. Add 1 drop of ferric chloride solution U. S. P. to 1 cc. of an aqueous solution of 8-hydroxyquinoline sulfate (0.1 Gm. in 10 cc. of water): a green coloration is produced. Add 1 drop of barium chloride solution U. S. P. to 1 cc. of an aqueous solution of 8-hydroxyquinoline sulfate (0.1 Gm. in 10 cc. of water): a white precipitate of barium sulfate is obtained. Add 1 cc. of normal

sodium hydroxide to 1 cc. of an aqueous solution of 8-hydroxyquinoline sulfate (0.1 Gm. in 10 cc. of water): a white crystalline precipitate is formed, which, on filtration, careful washing with cold water and drying in a desiccator, melts at 75 C. The free base has a saffron-like odor at room temperature; on sublimation or steam distillation, a phenol odor is noticeable. The picrate of the free base melts at 203 C.; it dissolves with difficulty in cold alcohol and is practically insoluble in benzene. With ferricyanide, the free base forms a definite crystalline compound of yellow prismatic needles, soluble with difficulty in cold water.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary.

CANNED FRUIT PRODUCTS (See Accepted Foods, 1939, p. 70).

Tyrrell and Garth, Inc., Houston, Texas.

GARTH BRAND TEXAS MAGNOLIA BREAKFAST FIGS, canned fresh figs packed in a light refined corn sugar (dextrose) and cane sugar (sucrose) syrup.

Analysis (submitted by manufacturer).—Moisture 62.4%, total solids 37.6%, ash 0.2%, fat (ether extract) 0.1%, protein (N \times 6.25) 0.5%, reducing sugars (as dextrose) 31.2%, invert sugar 22.8%, sucrose 8.0%, crude fiber 0.8%, carbohydrates other than crude fiber (by difference) 36.0%.

Calories.—1.47 per gram; 42 per ounce.

CHOCOLATE, COCOA AND CHOCOLATE FLAVORED BEVERAGE BASES (See Accepted Foods, 1939, p. 367).

Rockwood & Co., Brooklyn.

ROCKWOOD'S LOFAT BRAND COCOA, powdered cocoa containing not more than 1 per cent of cocoa butter, for special low fat diets.

Analysis (submitted by manufacturer).—Moisture 4.3%, total solids 95.7%, ash 6.1%, fat (ether extract) 0.4%, protein (nonalkaloidal N \times 6.25) 25.2%, crude fiber 5.7%, carbohydrates other than crude fiber (by difference) 56.0%, total nitrogen (N) 4.7%, alkaloidal nitrogen 0.7%, organic nonalkaloidal nitrogen 4.0%, total alkaloids 2.96,* theobromine (Wadsworth method) 2.62%,† caffeine by difference 0.34%.

Calories.—3.28 per gram; 93 per ounce.

FATS AND OILS (See Accepted Foods, 1939, p. 30).

A. P. Catsacoulis & Co., Metelin, Greece. Product distributed in the United States by Standard Products Co., Importer and Wholesale Grocer, Boston.

GLORIA BRAND PURE OLIVE OIL, the fixed oil obtained from ripe olives grown in the island of Metelin, Greece, conforming to U. S. P. standards for pure olive oil.

Analysis (submitted by manufacturer).—Specific gravity at 25 C. 0.912, index of refraction at 20 C. 1.469, saponification number 192, iodine number 85, acid number (cubic centimeters of N/10 alkali required to neutralize 10 Gm. of oil) 3.9, solidifying point of fatty acids 23.1 C, cottonseed oil absent, peanut oil absent, sesame oil absent, tcaseed oil absent.

Calories.—9 per gram; 256 per ounce.

Conti Products Corp., New York.

CONTI BRAND VIRGIN OLIVE OIL, imported Italian first cold pressed olive oil (U. S. P.).

Analysis (submitted by manufacturer).—Specific gravity at 25 C. 0.910-0.915, refractive index at 25 C. 1.46, saponification number 192, iodine number 83.5, free fatty acids as oleic acid 0.30, solidification point of fatty acids 23 C., unsaponifiable matter 0.8, cottonseed oil none, Sesame oil none, rape seed oil (Valents test) none, tea seed oil none, peanut oil none, sulfur none.

Calories.—9 per gram; 256 per ounce.

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939, p. 295).

The Chicago Dietetic Supply House, Inc., Chicago.

CELLU BRAND BEET JUICE, canned beet juice expressed from mature, partially cooked beets, packed without added water, sodium chloride or sucrose.

Analysis (submitted by manufacturer).—Moisture 91.7%, total solids 8.3%, ash 0.57%, fat (ether extract) 0.1%, protein (N \times 6.25) 0.6%, crude fiber none, invert sugar 1.1%, sucrose 5.1%, starch none, undetermined carbohydrates (by difference) 0.8%, carbohydrates other than crude fiber (by difference) 7.0%.

Calories.—0.31 per gram; 8.8 per ounce.

* Total alkaloids were determined according to the method of Moir, D. D., and Hinks, E.: The Determination of Total Alkaloids in Cocoa, Analyst 60: 439 (July) 1935.

† Theobromine was determined according to the method of Wadsworth as described in Allen, A. H.: Commercial Organic Analyses, ed. 5. Philadelphia, P. Blakiston's Son & Co., 1933, vol. 7, p. 602.

GRAIN PRODUCTS (See Accepted Foods, 1939, p. 95).

Pillsbury Flour Mills Company, Minneapolis.

PILLSBURY'S WHEAT BRAN, heat-treated coarsely flaked milled bran.

Analysis (submitted by manufacturer).—Moisture 8.5%, total solids 91.5%, ash 6.5%, protein (N \times 6.31) 17.2%, fat (ether extract) 3.5%, sucrose 4.5%, reducing sugars as dextrose 0.1%, crude fiber 10.5%, carbohydrates other than crude fiber (by difference) 53.8%, phosphorus (P) 1.48 per cent, iron (Fe) 9 mg. per hundred grams.

Calories.—3.15 per gram; 89 per ounce.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156).

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT BRAND CHOPPED APRICOTS, canned, chopped, cooked apricots prepared from unsulfured dried fruit.

Analysis (submitted by manufacturer).—Moisture 73.9%, total solids 26.1%, ash 1.1%, fat (ether extract) 0.1%, protein (N \times 6.25) 1.3%, crude fiber 0.9%, carbohydrates other than crude fiber (by difference) 22.7%, specific gravity 1.109.

Calories.—0.97 per gram; 28 per ounce.

Libby, McNeill & Libby, Chicago.

LIBBY'S BRAND HOMOGENIZED BABY FOODS FORMULATED COMBINATION No. 8, containing bananas, apples and apricots with a small amount of added water.

Analysis (submitted by manufacturer).—Moisture 85.5%, total solids 14.5%, ash 0.5%, sodium chloride 0.04%, fat (ether extract) 0.01%, protein (N \times 6.25) 0.5%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 13.2%, calcium (Ca) 0.009%, phosphorus (P) 0.024%, iron (Fe) 0.0016%, copper (Cu) 0.00020%.

Report of titration test (1939) indicates that this product contains 0.022 mg. of ascorbic acid per gram, 0.62 per ounce. Protocols of biologic assay (1939) indicate that this product contains approximately 9 U. S. P. units of vitamin A per gram, 226 per ounce; and 0.13 Sherman-Bourquin unit of vitamin G (riboflavin) per gram, 3.7 units per ounce. Rat growth tests have demonstrated measurable amounts of vitamin B₁ (thiamin).

Calories.—0.56 per gram; 15.9 per ounce.

Libby, McNeill & Libby, Chicago.

LIBBY'S BRAND HOMOGENIZED BABY FOODS FORMULATED COMBINATION No. 9, containing peas, spinach and green beans with a small amount of added sodium chloride.

Analysis (submitted by manufacturer).—Moisture 91.5%, total solids 8.5%, ash 1.1%, sodium chloride 0.6%, fat (ether extract) 0.1%, protein (N \times 6.25) 2.3%, crude fiber 2.5%, carbohydrates other than crude fiber (by difference) 2.5%, calcium (Ca) 0.041%, phosphorus (P) 0.045%, iron (Fe) 0.0019%, copper (Cu) 0.00022%.

Report of titration test (1939) indicates that this product contains 0.047 mg. of ascorbic acid per gram, 1.33 per ounce. Protocols of biologic assay (1939) indicate that this product contains approximately 22.5 U. S. P. units of vitamin A per gram, 639 per ounce; and 0.25 Sherman-Bourquin unit of vitamin G (riboflavin) per gram, 7.1 units per ounce. Rat growth tests have demonstrated measurable amounts of vitamin B₁ (thiamin).

Calories.—0.20 per gram; 5.7 per ounce.

The Borden Company, New York.

BIOLOC, a modified milk for infant feeding prepared from whole milk, skimmed milk and lactose (the mixture being evaporated), with added thiamine hydrochloride, cod liver oil concentrate and ferric citrate and the whole homogenized and heat processed.

Analysis (submitted by manufacturer).—Moisture 73.0%, total solids 27%, ash 1.2%, fat 4.6%, lactose (by difference) 15.7%, protein (N \times 6.38) 5.4%, available iron (*J. Biol. Chem.* 110: 685 [Aug.] 1935) from 0.38 to 0.56 mg. per fluidounce.

Protocols of biologic assay submitted by the firm [1940] showed that the product contains not less than 125 U. S. P. units of vitamin A, 4.0 international units of thiamine and 21 U. S. P. units of vitamin D per fluidounce; 2,000 U. S. P. units of vitamin A, 65 international units of thiamine and 340 U. S. P. units of vitamin D per can (16 fluidounces).

Calories.—40 per fluidounce, 624 per can (16 fluidounces).

SUGARS AND SYRUPS (See Accepted Foods, 1939, p. 324).

American Syrup & Preserving Company, Nashville, Tenn.

CRYSTAL FLAKE BRAND SYRUP, a mixture of corn syrup and granulated sugar syrup, artificially flavored with vanillin and coumarin.

Analysis (submitted by manufacturer).—Moisture 23.5%, total solids 76.5%, ash 0.2%, protein (N \times 6.25) 0.03%, reducing sugars before inversion (polarimetric method) 33.6%, reducing sugars after inversion (polarimetric method) 35.0%, sucrose (polarimetric method) 1.4%, dextrose (modification of Barfoed copper reduction method) (dry basis) 23.6%—fresh basis (calculated) 18.1%, maltose (dry basis) 35.2%, fresh basis (calculated) 26.9%, dextrin (by difference) 29.8%.

Calories.—3.05 per gram; 87 per ounce.

Heyl Brothers Company, Philadelphia.

HEYL'S BRAND TABLE SYRUP, consisting of 90 per cent corn syrup and 10 per cent cane refiners' syrup.

Analysis (submitted by manufacturer).—Moisture 21.7%, total solids 78.3%, ash 0.8%, nitrogen 0.015%, reducing sugar before inversion (fresh basis) 32.4%, total carbohydrates (by difference) 77.4%.

Calories.—3.1 per gram; 88 per ounce.

SATURDAY, AUGUST 17, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

FOOD AND THE WAR

The maintenance of the food supply of the army and of the civilian population of the country in a time of emergency is as important a question as any of the questions which may confront our leaders in times of rapid action and stirring events. In World War I every foreign country early appointed a food commission to control this problem. Early in 1917 THE JOURNAL emphasized the advisability of appointing at once in this country an appropriate scientific body to advise on such questions. The experience of many a foreign country after the war showed how inefficient and futile had been some of the considerations given to these vital problems. In the Netherlands and Denmark people were deprived of important sources of vitamin A in order that butter might be sold to other countries. As a result, numerous children developed xerophthalmia and similar conditions. In Germany the effects of malnutrition resulting from the blockade became apparent later in increased cases of tuberculosis among those

who were children at the time of the war. Today German writers are emphasizing the necessity for control of nutrition as basic to the winning of any conflict.

It is no secret that problems of maintenance of the food supply are already serious in the warring countries. Indeed, Great Britain has begun a meatless ration for some of the days of the week, inclining largely toward a diet of eggs, milk and vegetables. In a recent communication a German writer points out that the German diet must depend considerably during the forthcoming months on bread and potatoes and that it is necessary under such circumstances that the bread be a whole grain bread. Recently British authorities have appointed a food commission to control food in the British army and among the British people, and already it has been decided to prepare a bread fortified with vitamin B₁ and calcium and to offer this for sale at a price similar to that for white bread. Moreover, British authorities have been urging cooperation of the Ministry of Food with the Ministries of Health and Agriculture to develop a national policy for control of the food supply.

In World War I the Surgeon General of the army early in the mobilization of the drafted army took steps leading toward the formation of a division in his office charged with the duty of advising on all questions relating to the nutrition of the soldier. The importance of nutrition was recognized early, yet the Quartermaster General was opposed to the establishment of nutrition officers in camp and it required six months before the Secretary of War authorized a food division for the army. The situation which confronts us today indicates the need for prompt action with regard to food and nutrition as a part of our current efforts toward preparedness. The National Research Council has a subcommittee on nutrition which is working on the problem of emergency and standard rations for the armed forces. The question of food for the soldier is still primarily in the division of the Quartermaster's office, but the Surgeon General of the army is equally concerned with the question of feeding the invalid soldier and with the feeding of troops for the prevention of illness. It is understood that two different divisions of the Advisory Commission on National Defense have set up subcoordinators who will be concerned with the problems of food. One of these divisions is that concerned with agriculture, the other that concerned with the consumer. There does not seem to be any evidence that any effort has been made to coordinate in any manner the work of these different advisory bodies, nor is it apparent from the evidence thus far available that modern dietetics and leading authorities in the field have been called into service.

The fundamental importance of good nutrition not only for those engaged in military services but for the population as a whole as the source of military units needs no argument in its behalf. What is needed is suitable coordination in Washington of all the various

bodies that will be concerned with the nutrition of the nation. Such coordination can be brought about properly only by adequate representation of medicine, which includes scientific nutrition, in the Advisory Commission on National Defense.

NEUROCIRCULATORY ASTHENIA IN SOLDIERS

The appearance of the second edition of Sir Thomas Lewis's "The Soldier's Heart and the Effort Syndrome"¹ focuses the attention of physicians once more on one of the most frequent causes of invalidism among soldiers. "Soldier's heart," "the irritable heart of soldiers," "disturbed action of the heart," "effort syndrome" and "neurocirculatory asthenia" is not a disease. It is rather a complex of characteristic neurovascular symptoms, which occur with sufficient regularity to justify grouping into a definite syndrome. This condition is not an organic disease of the heart or a clinical entity with definite pathologic appearances. Neither is it peculiar to war conditions. Modern warfare with all its horrors, the physical and emotional strain and the constant fear of death which it invokes is bound to reap a rich harvest of victims of neurocirculatory asthenia. The extension of the horrors of war to the civilian population multiplies the cases beyond measure. In the war of 1914-1918, Sir Thomas Lewis states, for every four wounded there was one cardiovascular case in the British Expeditionary Force. Seventy thousand had reported sick and were classed as cardiovascular by the summer of 1918, and 44,000 soldiers with effort syndrome became pensioners. Actually no more than one out of six of these soldiers suffered from disease of the heart. The rest represented cases of "effort syndrome."

MacLean in 1867 and Meyers in 1870 wrote of the "irritable heart of soldiers" in the British army, while Da Costa described its occurrence in our Civil War. Da Costa pointed out that the symptoms were frequently present before enlistment. He stressed fever, diarrhea, wounds and the arduous existence of the soldier as etiologic factors. He gave the advice "not to send back soldiers just convalescent from fevers or other acute maladies too soon to active work" and "that recruits, especially very young ones, be as far as practicable exercised and trained in marches and accustomed to fatigue before they are called upon to undergo the wear and tear of actual warfare."

To differentiate the condition from organic disease of the heart the English classified these cases as "disturbed action of the heart (D. A. H.)." The effect of suggesting "something wrong with the heart" in a condition of undoubted neurogenic character had anything but a salutary effect on the patients. For this reason, and because the symptoms resembled those of fatigue following effort in normal persons, Lewis gave

it the name "effort syndrome." The name "neurocirculatory asthenia" was suggested by a team of medical reserve corps officers of the American army² sent to Colchester, England, to study the condition with Sir Thomas Lewis. They felt that the symptoms comprising effort syndrome in normal persons are not exactly the same as those observed in neurocirculatory asthenia.

While the basic mechanism of neurocirculatory asthenia has not been elucidated, the tendency of students of the syndrome is to regard it as psychogenic—a functional disorder of the autonomic nervous system. Given a neuropathic predisposition based on hereditary and constitutional inadequacy, many factors can assume the role of exciting or initiating agents. Among these, infectious or physical agents and the psychic strain of war are most important. The syndrome is characterized by dyspnea, fatigue and exhaustion, palpitation or heart consciousness, fainting, giddiness, headache, sweating, blueness or mottled coloring of the hands, dermatographia and a variety of neurovascular phenomena. The pulse at rest and in sleep is normal but is easily accelerated by emotion or exercise and is abnormally slow in its return to normal after exercise. Blood pressure is as a rule normal at rest but exhibits the same exaggerated response to exercise and emotion as does the pulse. The electrocardiogram does not reveal any structural changes. The symptom phosphaturia, so commonly observed in neurotic patients, is common especially after light exercise. The diagnosis of the syndrome presents few difficulties. Its differentiation from organic disease of the heart, however, calls for special training and experience in cardiology. The diagnostic problem likewise involves the recognition of possible associated disease such as pulmonary tuberculosis, exophthalmic goiter or malaria. The electrocardiogram, the roentgenogram and previous training and experience in cardiology should eliminate most of the earlier errors.

Undoubtedly the most important phase in the treatment of this condition is prevention. Prophylaxis should properly begin at the time of enlistment and in the training camps. The faulty examinations in the last war are clearly illustrated, as pointed out by Lewis, by the fact that nearly half the patients invalided for effort syndrome or heart disease developed the symptoms before joining the forces and more than half developed them before their training was complete. "There is not the slightest doubt," states Lewis, "that adequate examination would have eliminated most of these men, would have kept them in useful employment, would have spared them much suffering, would have saved hospital space and large funds of the Ministry of Pensions. Such cases were six or seven months in training, five months in hospital, and gave in return 2.2 months of full and 1.5 to two months light duty." Experience in the last war demonstrated that the

2. Oppenheimer, B. S.; Levine, S. A.; Morison, R. A.; Rothschild, M. A.; St. Lawrence, W., and Wilson, F. N.: *Report on Neurocirculatory Asthenia and Its Management*, Mil. Surgeon, April and June 1918.

prognosis on the whole was more favorable when treatment was instituted early. Prolonged rest in bed and digitalis had little if any effect on the course of the ailment. A correct psychologic approach to a condition with a pronounced mental aspect is essential to success. The patient above all must be reassured that he is not suffering from heart disease. The treatment of infections and of foci of infections is important. The regimen of graded exercises, as developed by Lewis, has been preeminently successful in restoring most of these patients to a more or less normal state. It has been useful both for sorting patients as to their reaction to exercise and in curing their symptoms. After a short rest in bed this regimen is initiated by short drills outdoors supplemented by hikes and games. The average stay at the hospital under this plan has been shortened from an average of 5.3 months to some five or six weeks.

IONIZED CALCIUM IN MILK

Much information is available about the inorganic salts of milk, but more is yet to be learned about the forms in which these constituents occur and the manner of their utilization by the body. In many respects our knowledge of the physical chemistry of milk is particularly incomplete. Clark,¹ for example, has pointed out that important mathematical constants which are essential to a thorough understanding of the buffer systems of milk are not available. Information about the equilibrium between the various forms of calcium and of the concentration of ionized calcium in milk is especially desirable. Such information not only is important to a thorough understanding of the physiology of milk secretion but also finds application in studies that might shed light on factors involved in the utilization of the calcium in milk.

Recently Nordbø,² with the help of ingenious methods, made a study of the concentration of ionized calcium, as well as magnesium, in cow's milk. The values calculated for the concentration of ionized calcium in the ultrafiltrate of milk approximate the values for total calcium in the ultrafiltrate of blood serum. While practically all the calcium in the ultrafiltrate of blood serum is present in the form of calcium ions, only 20 per cent of the total calcium in the ultrafiltrate of milk is present in the ionic form. It is remarkable that the concentration of citric acid and lactose in the ultrafiltrate of milk seems to be of the order of magnitude necessary to account for the non-ionized calcium as well as for the non-ionized magnesium. The combination of calcium with citric acid, as well as the rather unusual combination of calcium with lactose, results in the formation of non-ionized calcium compounds. These observations may explain how the risk of a loss of calcium through phosphate precipitation in the intestine is reduced. It also may be recalled that there is evidence that the

presence of lactose in the diet favorably influences the utilization of calcium by the growing animal.³ Moreover, there is evidence that lactose in the diet, in contrast to sucrose or dextrin, is able to prevent tetany in thyroparathyroidectomized dogs, an observation which supports the view that milk sugar may be important in calcium metabolism.⁴ With regard to the effect of citric acid on calcium metabolism, it may be recalled that the addition of a citric acid and sodium citrate mixture to a rachitogenic diet can alter the diet to such an extent that it no longer produces rickets.⁵

In the presence of additional citric acid, cow's milk yields a more finely divided casein precipitate, and this phenomenon may be due to a suppression of the number of calcium ions present. As pertinently pointed out by Nordbø, if this is true a similar result might be obtained by the addition of extra lactose. In any case, the fact that lactose combines with calcium to form soluble, non-ionized compounds would seem to indicate that milk sugar, like citric acid, not only serves as a source of food energy but also is a factor in influencing the state of calcium in milk. This observation may well merit further study by those who are interested in learning more about the physicochemical properties of milk.

Current Comment

CLOTHING AND AIR CONDITIONING STANDARDS

The "double standard" of temperature for men and women complicates the problems of the engineer and increases the expense of heating and cooling office buildings. Women prefer higher temperatures than men for comfort not so much because of any difference in constitution as for the clothing they wear. Yaglou¹ undertook some unique experiments to establish this point. The mean skin temperature of women under ordinary conditions in a room of 71.5 F. and 30 per cent relative humidity with 20 feet per minute air movement was about 2 degrees Fahrenheit lower than that of men. The feet and hands of women averaged 5 degrees cooler than men's, while the trunk was only 0.5 degree cooler than men's. When most of the men in a room were comfortable the women generally were cold. To make the women comfortable the room temperature had to be raised to about 76 F.; then the men began to complain. When the men and women were dressed alike they were comfortable at about the same temperature. When both sexes wore a minimum of clothing, 84 degrees was satisfactory for both sexes. Men were dressed in women's summer clothing; then they demanded a temperature of 80 degrees, which was about the same as that preferred by women similarly

dressed. Women were dressed in men's winter clothes; then the comfortable air temperature for them went down to 70.5 F., or a degree lower than that preferred by men wearing the same clothes. In almost all instances comfort was associated with a mean skin temperature between 91.5 and 93 F. in both men and women, regardless of the air temperature, the amount of clothing and the season of the year in which the experiments were done. The mean surface temperature of the clothes and the exposed skin varied from 67.6 to 91.9 degrees under comfortable conditions. The wearing of additional clothes always increased the skin temperature of all parts of the body, the covered or the exposed, and decreased the surface temperature of the clothing worn. Yaglou concluded that differences in comfort standards between men and women are primarily due to differences in dress and can be reconciled by adjustments of clothing, according to susceptibility to cold or heat. If women in winter would dress in clothes comparable in warmth to those of men, they would be comfortable in temperatures of about 70 instead of 76 at present. If men would take off their coats, vests and collars in summer, buildings would not have to be cooled much below 85 degrees instead of 76 to 80 at present. Thus much of the difficulty experienced with sharp temperature contrasts between the sexes could be alleviated simply by adjustments of clothing.

ARCHIVES OF SURGERY ISSUES SPECIAL NUMBER HONORING DEAN LEWIS

The issue of the *Archives of Surgery* for August is a "Dean Lewis Number," prefaced with a photograph showing J. M. T. Finney, Dean Lewis and Harvey Cushing in 1926. The volume begins with a brief biographic note picturing Lewis as a master teacher with a marvelous personality, the product of the teaching of such masters as Billings, Herrick, Senn and Bevan in the medical school and Fenger, Harvey, Ochsner, Andrews and Harris in the hospital. Almost immediately after completing his internship, Dean Lewis became a teacher. He has traveled far and wide to lecture to medical societies, for which he has been constantly in demand. He has talked particularly about ductless glands, the transplantation of tissue, bone tumors, neurosurgery and the pathologic conditions affecting the breast. Wherever he taught before his retirement he was surrounded by admiring listeners, and his students at Johns Hopkins Hospital were constantly amazed at his mastery of his subject and his operative facility. It is not surprising that many leaders in the field of medicine and surgery should unite to do him honor. The special issue of the *Archives of Surgery* contains thirty-one scientific articles by notable investigators, teachers and clinicians whose places of residence reflect the entire nation and whose positions of leadership reflect all of medical science. Dr. Lewis was himself the editor of the *Archives of Surgery* from its establishment in 1920 until his retirement as editor emeritus last year. The preparation of the special number in his honor is a well merited recognition of his distinguished services as surgeon, investigator, teacher, author and editor.

Medical Preparedness

IN THIS SECTION OF THE JOURNAL EACH WEEK WILL APPEAR OFFICIAL NOTICES BY THE COMMITTEE ON MEDICAL PREPAREDNESS OF THE AMERICAN MEDICAL ASSOCIATION, ANNOUNCEMENTS BY THE SURGEON GENERALS OF THE ARMY, NAVY AND PUBLIC HEALTH SERVICE, AND OTHER GOVERNMENTAL AGENCIES DEALING WITH MEDICAL PREPAREDNESS, AND SUCH OTHER INFORMATION AND ANNOUNCEMENTS AS WILL BE USEFUL TO THE MEDICAL PROFESSION.

QUESTIONNAIRES RETURNED

Almost 180,000 questionnaires for the submission of personal information to be associated with any mobilization of the medical profession that may be required have now been put in the mails and, as we go to press, almost 80,000 of these have been returned. It is inter-

esting to observe the varying percentages of physicians in various states who have replied. Nebraska leads all other states with more than 71 per cent, whereas New Mexico, Mississippi and Tennessee have made the smallest return. From week to week the record of returns will be listed, as it is highly important that there be a card in the system of every physician in the United States regardless of his ability to render military service.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 8613 has been reported to the House without amendment, providing that any person who served as a member of the Army Nurse Corps or of the Navy Nurse Corps during the World War and continuously thereafter until May 13, 1926, and who was, prior to June 20, 1930, separated from said corps by reason of physical disability incurred in line of duty, shall, on her application therefor, be entitled to be placed on the retired list of the Nurse Corps of which she was a member, her retired pay becoming effective on the date of receipt by the Secretary of War or the Secretary of the Navy, as the case may be, of such application or the date of enactment of this bill, whichever is later.

Bills Introduced.—S. 4224, introduced by Senator Sheppard, Texas, and H. R. 10278, introduced by Representative May, Kentucky, propose that in time of war or during an emergency declared by the Congress the Secretary of War may, in his discretion, dispense with any of the examination for promotion

in the Regular Army of officers of the Medical, Dental and Veterinary Corps, except the physical examination. H. R. 10223, introduced by Representative Vinson, Georgia, proposes to authorize the Secretary of the Navy to establish naval hospitals at the naval air station at Jacksonville, Fla., and San Juan, Puerto Rico; the submarine base, Coco Solo, Canal Zone; the naval station, Guantanamo Bay, Cuba, and the Marine Barracks, Quantico, Va. H. R. 10239, introduced by Representative Courtney, Tennessee, proposes to authorize the Administrator of Veterans' Affairs to pay to Dr. H. A. Gant, Columbia, Tenn., the sum of \$50 per month as long as he shall live. The bill states: "The said Dr. H. A. Gant rendered high public service in various yellow fever epidemics in the South, and certain statistics kept by him were of material aid to those engaged in the yellow fever investigations in Cuba in the establishment of the theory of the transmission of yellow fever by the mosquito. The said Dr. H. A. Gant is now of advanced age and totally and permanently disabled." The bill was referred to the House Committee on World War Veterans' Legislation.

MEDICAL ECONOMIC ABSTRACTS

HEALTH SERVICE SYSTEM OF SAN FRANCISCO

Managers of the Health Service System for municipal employees and the employees of the Board of Education of San Francisco have issued a first annual report covering fifteen months of operation of a plan covering 15,000 persons. The information which follows is taken from that report.

The membership was made up of 9,809 employees, 3,124 adult dependents and 1,817 minor dependents. This was an average monthly membership during a period when there was a steady increase in members. The premium for each employee and adult dependent was \$2.50 a month. Minor dependents under 18 years of age were charged \$1.50 a month, and each additional minor dependent \$1 a month.

The percentage distribution of expenditures given in the first table was made from the total of the combined funds.

Of the total of \$355,232.77 disbursed for medical care, approximately 68 per cent went for doctor service, 23 per cent for hospitalization and 9 per cent for x-ray, clinical laboratory examinations, ambulance and physical therapy.

Nearly a quarter of a million dollars was paid to doctors during the first year for the treatment of 10,696 individuals. This is 73 per cent of the entire membership. Sixty-seven per

Thirteen hospitals received a total of \$81,422.80 for the hospitalization of 1,500 persons during the twelve months ended Sept. 30, 1939. The average cost per case was \$54.28.

Payment to the hospitals is made at the flat rate of \$7.20 a day, regardless of the amount of service used. In some so-called

Payment to Doctors and Value of Unit by Months

October 1938—September 1939		
Month and Year	Paid to Doctors	Value of Unit
October 1938	\$13,452.00	\$1.00
November 1938	17,603.50	1.00
December 1938	38,063.00	1.00
January 1939	17,940.75	0.50
February 1939	18,874.87	0.65
March 1939	17,801.04	0.50
April 1939	18,948.17	0.54
May 1939	19,543.34	0.57
June 1939	19,630.78	0.57
July 1939	19,174.62	0.66
August 1939	20,273.08	0.65
September 1939	20,451.42	0.67
Total	\$241,756.57	\$0.66

"come and go" cases, in which the patient is confined only part of the day, the full daily rate is not charged.

This entitles the patient to a ward bed, meals, general nursing care, floor supply of drugs and dressings, x-ray and clinical laboratory examinations, use of operating room, administration of anesthetic and various other services. A patient may select a private or semiprivate room by paying to the hospital the difference between the regular ward rate and the rate for any other room he may choose. Many patients chose the higher priced accommodations.

This year's experience has shown that the cost of providing hospital benefits was 46 cents per subscriber monthly, exclusive of overhead.

In November 1939 several changes were made in the plan. The rate of contribution for all minor dependents was raised to \$1.50 a month and the following changes in the service were adopted to affect dependents only:

1. Treatment was limited to one year for any one condition, illness or injury.
2. The rate for minor dependents was increased to \$1.50 a month regardless of the number enrolled by the employee.
3. In the future all dependents must have a medical examination before being admitted to the System and any pathologic

Percentage Distribution of Expenditures

Doctors	57.9
Hospitals	19.5
X-ray laboratories	3.8
Clinical laboratories	2.2
Ambulance	0.4
Physical therapy	1.3
Medical overhead	5.3
Nonmedical overhead	7.9
Equipment and alterations	0.5
Unexpended balance	1.2
	100.0

cent of the employees had the service of a doctor by the end of September 1939, and that percentage went up to 75 by the end of the calendar year. It was recognized that there was considerable abuse of the system. Nine hundred and eighty-six local doctors and ninety-four out of town doctors participated in the Health Service.

The chief complaint of the doctors has been that the monthly value of the unit of service was too low.

condition existing at that time will have to be corrected before the person is admitted; or the person may be admitted but the Health Service will not be responsible for the bills for treatment of that condition.

4. No minor dependent will be admitted until attaining the age of 1 year.

The number of office visits for either dependents or employees for which the Service will be responsible has been limited to five a month. This was a counter proposal to the one made by the doctors' committee that the patient be required to pay for the first two office visits and the first two home visits. Henceforth, all subscribers are to be restricted to the service of one doctor a month except with the consent of the medical director. This was to prevent patients from shopping around for the same condition. Refractors were also eliminated from the benefits beginning with Nov. 13, 1939. The fee schedule was revised to permit the general practitioner to receive more remuneration for his services.

The administration costs were 13.2 per cent, and it is believed that this can be reduced in the future. Demands of osteopaths and chiropractors and practitioners of drugless therapy for a right to practice under the plan are in course of litigation.

The average cost per employee member monthly for medical services is \$1.87, adult dependents \$2.28, and for minor dependents \$2.05.

AUTOMOBILE AND MEDICAL EXPENSES

That the whole question of the ability to obtain medical care is confused with the fact that most people buy what they are sold rather than what they need is illustrated by a comparison of the expenditures among low income classes for automobile purchases and operation with those for medical care. Statistics

TABLE 1.—Percentage of White Families That Reported Automobile Ownership in 1935-1936, at Selected Income Levels

Income Class	West Central	Rocky Mountain
\$ 750-\$ 999	38	65
\$1,250-\$1,499	66	76
\$1,750-\$1,999	72	79
\$2,250-\$2,499	77	86
\$3,000-\$3,499	85	78
\$4,000-\$4,999	90	94
\$5,000 and over	89	78

TABLE 2.—Estimated Average Total Automobile Expenditures Incurred by Automobile Operators, for White Families, at Selected Income Levels

Income Class	West Central	Rocky Mountain
\$ 750-\$ 999	\$ 78	\$ 88
\$1,250-\$1,499	154	191
\$1,750-\$1,999	226	228
\$2,250-\$2,499	258	277
\$3,000-\$3,499	306	283
\$4,000-\$4,999	329	429
\$5,000 and over	542	510

TABLE 3.—Average Expenditures for Medical Care by Families

Income Class	West Central	Rocky Mountain
\$ 250-\$ 499	\$ 25	\$ 42
\$ 500-\$ 749	26	38
\$ 750-\$ 999	44	64
\$1,000-\$1,249	51	67
\$1,250-\$1,499	51	93
\$1,500-\$1,749	83	85
\$1,750-\$1,999	87	92
\$2,000-\$2,249	113	112
\$2,250-\$2,499	84	111
\$2,500-\$2,999	104	103
\$3,000-\$3,499	108	139
\$3,500-\$3,999	167	107
\$4,000-\$4,999	129	201
\$5,000 and over	230	194

are taken from a "Study of Consumer Purchases" issued by the United States Department of Labor, Bulletins 646 and 648. The middle sized cities in the West Central and Rocky Mountain districts are used for comparison because the bulletins mentioned presented figures from these two localities in comparable form (table 1).

In these cities the expenditures incurred by those who operated automobiles were as given in table 2.

The expenditures for medical care are given in a somewhat different manner but permit comparison (table 3).

DEATH RATES CONTINUE TO FALL

In spite of depressions, economic changes and social handicaps, death rates continue to fall. Comparisons of vital statistics between the United States and European countries are always unfair, owing to the fact that the United States is almost as large as the whole of Europe and presents an almost equal diversity of conditions. The true comparison should be between certain localities in the United States and similar ones in Europe. Recent reductions in infant mortality illustrate this point.

While the reductions for the entire registration area from 1933 (when for the first time all states were in that area) to 1939 (provisional rate) has been from 58 per thousand live births to 48, the latter figure by no means represents the situation in certain states where economic and medical conditions have had an opportunity to produce their best results.

In 1937 New Jersey was the only state to have an infant death rate below 40, the rate being 39. In the next year New Jersey was joined by Nebraska with a rate of 36 and Oregon with 39. The provisional rate for 1939, which is seldom changed much by later figures, shows thirteen states below 40, with the following rates:

Connecticut	36
Illinois	37
Indiana	39
Iowa	39
Kansas	39
Massachusetts	39
Minnesota	35
Nebraska	37
New Jersey	38
New York	39
Oregon	37
Utah	39
Washington	37

The tuberculosis rates show similar characteristics, the decline for the entire registration since 1933 (when all states were, for the first time, included) having been from 59.5 per hundred thousand of estimated population to 48.9 in 1938. In 1933, however, there were only four states with a rate below 30. These were Iowa 26, Nebraska 22.2, North Dakota 24.4 and Utah 21.8. In 1938, however, there were seven states with the following rates:

Idaho	22.1
Iowa	19.2
Kansas	22.9
Nebraska	16.6
New Hampshire	29.0
North Dakota	19.8
Utah	19.3
Wyoming	25.5

Perhaps the most significant feature of these statistics is the comparatively rapid decline of death rates in the states already having the lowest rate. Every student of vital statistics knows that as a usual thing, unless some specific method of treatment (as in the case of diphtheria) is discovered, the conquest of a disease is slower as the death rate declines. That this does not seem to be true with regard to tuberculosis would indicate that this disease is really on the way to join numerous other plagues that have ceased to be a significant threat to the life of mankind.

Compiled from Vital Statistics, Special Reports, Department of Commerce, Bureau of Census 9: 835 (July 10), 853 (July 12) 1940.

WOMAN'S AUXILIARY

The National Meeting in New York

At the Eighteenth Annual Session of the Woman's Auxiliary to the American Medical Association in New York, June 10 to 14, Mrs. Rollo K. Packard, President, presided with Mrs. Carlton F. Potter as convention chairman. The following officers were elected for 1940-1941:

President, Mrs. V. E. Holcombe, Charleston, W. Va.
President-Elect, Mrs. R. E. Mosiman, Seattle.
First Vice President, Mrs. Charles H. Werner, St. Joseph, Mo.
Second Vice President, Mrs. Don A. Epler, Newark, N. J.
Third Vice President, Mrs. Eustace A. Allen, Atlanta, Ga.
Fourth Vice President, Mrs. Arthur C. Jones, Boise, Idaho.
Recording Secretary, Mrs. John L. Bauer, Brooklyn.
Treasurer, Mrs. David W. Thomas, Lock Haven, Pa.

The national membership is 23,524, with sixty-six new auxiliaries this year. Mrs. J. Emerson Noll, chairman of credentials and registration, reported that the registration was 1,321.

California

The Solano County auxiliary, the fourth county organized this year, recently held its first meeting at Vallejo. Dr. Robert Glass Cleland, vice president of Occidental College, was guest speaker of the Los Angeles County auxiliary, April 23. His topic was "The Historian Looks at the Future." Mr. Robin Lampson of the extension department of the University of California reviewed his latest book, "Death Takes a Pair of Wings," at the Santa Cruz County auxiliary recently. The Sonoma County auxiliary at its March meeting heard book reviews by three of its members on "Medicine at the Cross Roads," by Bertram M. Bernheim, M.D., "The Patient's Dilemma," by Dr. Hugh Cabot and a discussion on "Experimentation in Meeting Medical Needs by Voluntary Action" by Martin W. Brown.

Georgia

The woman's auxiliary to the Georgia medical society held its annual meeting in Savannah. Mrs. Eustace A. Allen, the president, reported that last year one new district and seven counties were organized. The membership was increased from 549 to 632 members, the largest paid membership the auxiliary has ever had. Two hundred and ten *Hygeia* subscriptions were obtained and 24,000 copies of health literature on tuberculosis, venereal diseases, heart diseases, cancer, communicable diseases, maternal and child health and malnutrition were distributed. Twenty-two radio health talks were sponsored and 200 announcement blotters and fifty posters of American Medical Association radio programs were distributed; 151 programs on self education on health subjects were held among county auxiliaries; 187 members held the chairmanship of health in other organizations; thirty-nine health films were shown throughout the state, at schools, parent-teacher meetings, orphanages, industrial groups and the like. Twenty-five dollars was contributed during the year to this fund. One hundred and eight public relations programs were sponsored. The student loan fund was increased by \$209, making a total of \$2,079.51 now available for medical students.

Indiana

The Vigo County auxiliary of Terre Haute, with a membership of seventy-eight, has for two years sponsored occupational therapy work in the two Terre Haute hospitals. The salary of the teacher and the materials used are paid for by the auxiliary.

Iowa

The woman's auxiliary to the Iowa State Medical Society held its eleventh annual meeting in Des Moines. Dr. John I. Marker of Davenport gave an address on "Character and Personality Development."

Michigan

At a recent meeting of the Bay County auxiliary, Dr. Otto Ehrlich, an intern in one of the local hospitals, spoke on the life and work of his uncle, Dr. Paul Ehrlich, noted scientist and discoverer of arsphenamine.

Minnesota

The eighteenth annual meeting of the woman's auxiliary to the Minnesota State Medical Association was held in Rochester.

Malcolm McLean, Ph.D., director of the general college of the University of Minnesota, gave an address "Are the Schools or Trial?"

Missouri

Mrs. Paul F. Cole, president of the woman's auxiliary to the Missouri State Medical Association, in her annual report at St. Louis, recently stated that they were proud of their *Hygeia* record; having 155 more subscriptions this year than last year.

Oregon

Mid-Columbia County auxiliary entertained all women's groups in the district at a tea on May 16 at which Dr. John H. Fitzgibbon of Portland, delegate from Oregon to the American Medical Association, was guest speaker.

Texas

At the recent meeting of the Bowie-Miller counties auxiliary Mrs. Ralph Cross, president, presented each member with a cleverly arranged "report card" showing the member's attendance and the work done by the individual. The Bowie County auxiliary was awarded a prize of \$30, given by Dr. Preston Hunt of Texarkana for the auxiliary having the greatest percentage of members who read the *Texas State Journal of Medicine*.

The twenty-second annual session of the woman's auxiliary to the State Medical Association of Texas was held in Dallas in May. Mrs. S. H. Watson, president, presided. Guest speakers were Mrs. Rollo K. Packard, President of the Woman's Auxiliary to the American Medical Association; Dr. L. H. Reeves, Fort Worth, president, and Dr. Preston Hunt, Texarkana, president-elect of the state medical association, respectively. Six new county auxiliaries and one new district were organized during the year, and one district was reorganized. Close to 500 subscriptions to *Hygeia* were sold.

Mrs. Scott C. Applegate, San Antonio, has resigned as president of the auxiliary of the State Medical Association of Texas because of illness in her family; she will be succeeded by the first vice president, Mrs. William Hibbitts, of Texarkana. Mrs. Leslie Moore, Dallas, will serve as first vice president and Mrs. Ralph Cross of Texarkana as corresponding secretary. The state executive board meeting, scheduled to meet in July in San Antonio, has been postponed until September 10 and will be held in Fort Worth, with Mrs. Hibbitts as hostess.

Wisconsin

The woman's auxiliary to the Fond du Lac medical society at its meeting in May voted an appropriation for the girl scout troop which it sponsors and made plans to send several girls to summer camp. Money was donated to the Red Cross emergency fund.

Experiments in prepaid medical care in Douglas, Milwaukee and Rock counties were outlined by Mr. G. B. Larson, assistant secretary of the State Medical Society of Wisconsin in a lecture sponsored by the women's auxiliary to the Outagamie County Medical Society, May 27, at Appleton. More than 300 women representing the medical auxiliaries of Outagamie, Winnebago and Brown counties, as well as a large number of members of Appleton women's organizations, were present.

The Portage County Medical Society and the crippled children's division of the state department of public instruction recently conducted an orthopedic clinic at Stevens Point. Mrs. F. A. Marrs was in charge of local arrangements. Two hundred handicapped persons, ranging in age from infancy to the age of 21, were examined. Mrs. W. F. Cowan, another auxiliary member, was in charge of the noon luncheon, at which 370 persons were served.

Rock County auxiliary recently celebrated its tenth anniversary with a dinner in Janesville. Informal talks on the past history and future aims of the auxiliary were given by Mrs. C. N. Neupert of Madison, Dr. Jessie Allen of Beloit, Mrs. F. W. Pope of Racine, state president, and Mrs. C. A. Harper of Madison, present chairman of the archives and a past president of the state organization.

An auxiliary to the Sauk County Medical Society was organized, May 28. The wives of eleven physicians were present.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Harlow Brooks Clinical Conference.—The Fifth Harlow Brooks Memorial Navajo Clinical Conference will be held at the Sage Memorial Hospital, Ganado, August 26-28. Among the speakers will be:

- Dr. Fred H. Albee, New York, Biophysiological Relations of Treatment in Fractures of the Neck of the Femur; also Mosaic Inlays and Peg Grafts in Reconstruction Surgery.
- Dr. Max Thorek, Chicago, Electrosurgical Obliteration of the Gall-bladder.
- Dr. Henry H. Turner, Oklahoma City, Present Status of Endocrinology in General Practice.
- Dr. Charles E. Futch, Los Angeles, Sinus Pathology: When to Operate.
- Dr. William H. Daniel, Los Angeles, Infective Lesions of the Colon, as Ulcerative Colitis and Other Lesions.
- Dr. Ralph F. Palmer, Phoenix, The Evolution and Present Status of the Relationship Between Organized Medicine and the Industrial Commission in the Administration of the Workmen's Compensation Law in Arizona.
- Dr. Edwin Forrest Boyd, Los Angeles, Some Phases of Geriatrics.
- Dr. Buell H. Sprague, Los Angeles, Some Unpublished Ideas on Thyroid Surgery.

CALIFORNIA

Credit Information Service.—A central medical credit information service is being organized by the San Francisco County Medical Society for the use of members. This unit is the first step toward establishing a medical business center operated by the society, making available various services to members.

Personal.—Dr. Edwin S. Bennett, for more than four years medical director of Olive View Sanatorium, Olive View, has been appointed superintendent of the Los Angeles County General Hospital.—Dr. Karl Chester Gummess, Los Angeles, has been appointed medical director for the state relief administration, succeeding Dr. Albert E. Larsen, San Francisco, who resigned recently to become medical director for the Agricultural Workers Health and Medical Association.—Dr. Frank B. Young, Long Beach, has been made a member of the state board of health.

Society News.—Dr. Martin W. Debenham, San Francisco, discussed "Immediate Suturing of Tendons in Traumatic Wounds" before the Plumas-Lassen-Modoc Counties Medical Society in Susanville recently.—The Yuba-Sutter Counties Medical Society has been reorganized and will henceforth be known as the Yuba-Sutter-Colusa Counties Medical Society. The new society was recently addressed by Dr. Sterling Bunnell, San Francisco, on "Reconstruction of Hands."—Dr. Arthur A. Marlow, La Jolla, discussed "Leukemia and Related Disorders of the White Blood Cell" before the Hollywood Academy of Medicine, July 11.

ILLINOIS

Health Exhibits at State Fair.—The state health department will present two new exhibits in its annual health exposition at the Illinois State Fair in Springfield, August 17-25, in cooperation with the Public Service Company of Northern Illinois. One will depict the hazards of night driving and the inability of the eye to cope with these hazards. Dioramas, transparencies, working models, apparatus, street and highway lighting units and the scientific equipment used in research on the subject will be shown. The other exhibit shows 2,000 years of progress in the evolution of resuscitation from drowning, gas asphyxiation and electric shock. Dr. Hart E. Fisher, Chicago, chief surgeon of the public service company, will be in charge. Other features of the health department's exposition will be free blood tests, medical examination of children, exhibits on "contact" diseases and nutrition. A motion picture program will be presented daily.

Chicago

Rural Health Service.—Dr. Edward A. Piszczek has been temporarily appointed head of a new county health service for unincorporated areas and villages in Cook County which have no public health facilities. According to the newspapers, July 19, the appointment was believed to be for sixty days, when

a civil service examination is expected to be held to select a permanent head of the service. The new service was created in June with county and state funds.

Juvenile Home Psychiatric Department Installed.—New quarters for the department of psychiatry of the Juvenile Detention Home with expanded services in the treatment of these cases have been installed on the third floor of the court building at Ogden Avenue and Roosevelt Road, newspapers report. The new arrangement, under the direction of Dr. Paul L. Schroeder, state criminologist, will provide seven private offices for consultation with the youths brought in for mental examination, a staff office, ample space for clerical workers and records and waiting rooms. Instead of a large public waiting room, the waiting space has been divided into cubicles each accommodating four persons. Entrance to consultation offices will be private. All children will be given a physical examination in the court building instead of being taken to their neighborhood clinics as heretofore, making possible a complete medical and psychiatric report within twenty-four hours.

IOWA

Typhoid Carriers.—As a result of field investigations by the state department of health and efforts of attending physicians, five typhoid carriers have been brought under control in Iowa thus far in 1940, according to the state medical journal. In each instance an active case of the disease led to the suspicion of a carrier among the close contacts, it was stated. In one Iowa town several cases of typhoid were reported during the last two years. An investigation proved that a neighbor of the patients was harboring typhoid organisms.

Course on Care of the Newborn.—A three day post-graduate course on the care of the newborn will be held at the University Hospital, Iowa City, September 17-19, under the auspices of the state department of health and the State University of Iowa College of Medicine. The course will be limited to seventy-five physicians and no applications will be accepted after September 10. Lecturers will include:

- Dr. Julius H. Hess, professor of pediatrics at the University of Illinois College of Medicine, Chicago.
- Dr. Horton R. Casparis, professor of pediatrics at Vanderbilt University School of Medicine, Nashville, Tenn.
- Dr. Irvine McQuarrie, professor of pediatrics at the University of Minnesota Medical School, Minneapolis.

Dr. Edward N. Anderson, Iowa City, football coach at Iowa, will speak Tuesday evening.

MAINE

Society News.—Dr. Wilfrid J. Comeau, Bangor, addressed the Aroostook County Medical Society in Houlton, June 13, on "Cardiac Drugs—Their Use and Abuse."—The Oxford County Medical Association was addressed in Bethel recently by Drs. George L. Pratt, Farmington, and Harry Eugene Macdonald Jr., Portland, on organization affairs and head injuries, respectively.—Dr. Neil W. Swinton, Boston, discussed diseases of the rectum and anus before a recent meeting of the Piscataquis County Medical Association in Guilford.

MICHIGAN

New Chief in Charge of Tuberculosis.—Dr. Thaddeus M. Koppa, member of the staff of the bureau of epidemiology, state department of public health, since February 1939, has been appointed director of the tuberculosis division of the bureau. The division was formerly in charge of Dr. Arthur W. Newitt, who is now director of the bureau of epidemiology. Before coming to Michigan, Dr. Koppa served as director of the bureau of communicable diseases of the Wyoming State Department of Health.

Pollen Survey.—Arrangements have been completed for the organization in Michigan of one of the first general pollen surveys ever sponsored by a state health department. Thirty-nine cities will participate in the program, which has the support of northern Michigan recreational centers and the tourist and resort associations. B. H. Grigsby, instructor in botany at Michigan State College, has been engaged by the laboratories of the health department to read the pollen slides which will be exposed daily at all of the thirty-nine survey stations. Rudolph Lang has been appointed field agent for the survey. Control stations are to be established in southern Michigan where the pollen pollution is known to be heavy, probably at Detroit, Flint, Lansing, Grand Rapids, Grand Haven, St. Joseph, Coldwater and Hillsdale. Data obtained from these stations will serve as a check on that obtained from northern

Michigan centers. The health department points out in its bulletin that knowledge of the types and the distribution of pollen throughout the state will aid hay fever sufferers in selection of resorts where relief may be obtained.

MISSISSIPPI

State Journal Honors Early Physician.—The *Mississippi Doctor* for July was dedicated to Dr. John W. Monette, Washington, 1803-1851, the first physician in the state to be placed in the Hall of Fame of the state department of archives and history. At the recent annual session of the Mississippi State Medical Association a special display of memorabilia concerning Dr. Monette was shown under the joint auspices of the medical library of the state board of health and the state department of archives and history. The exhibit included a life-size portrait of Dr. Monette and was presented to the hall of fame during special ceremonies by the state medical association. In making the presentation Dr. James P. Wall, Jackson, then president of the association, identified Dr. Monette as physician, trail blazer in the control of yellow fever, and historian. Judge Gerard Brandon, Natchez, grandson of Dr. Monette, presented a biographic sketch of the physician. Dr. Monette received his preliminary medical education from his father, Dr. Samuel Monette, also a physician. He completed his medical course at Transylvania University, Lexington, Ky., receiving his diploma on March 21, 1825. Although Dr. Monette wrote extensively on many subjects, his chief claim to distinction as a student and historian rests on his "Valley of the Mississippi," published in two volumes by Harper & Brothers in 1846. His greatest literary undertaking was his "Physical Geography of the Mississippi Valley." He died before the work was published.

NEW YORK

Transfusion Service Organized.—A complete transfusion service to make available better treatment and to make possible further research was inaugurated July 1 in the Hazard Laboratory of Memorial Hospital, Syracuse. The service will be available to the University, Memorial, City and Psychopathic hospitals under the direction of Dr. John B. Alsever. It was made possible by an initial grant of \$5,000 from the Hendricks Research Fund of the Syracuse University Medical College. It will function on a twenty-four hour basis and will provide preserved adult blood, fresh adult blood, blood plasma and preserved placental blood. A list of blood donors will also be maintained, but it is expected that suitable preserved blood will usually be available, and the patients can repay the service by furnishing blood through friends and relatives, regardless of their blood group. Professional donors will be paid as at present, but otherwise patients will pay only a small service charge.

New York City

Theodore Weicker Dies.—Theodore Weicker, chairman of the board of E. R. Squibb & Sons, New York, pharmaceutical manufacturers, died in Greenwich, Conn., August 7, aged 79. Mr. Weicker, a native of Germany, came to America in 1887 and immediately became a citizen. On his recommendation the German firm of E. Merck established a New York branch, in which he was managing partner for fifteen years. Aside from conducting his business he took degrees in pharmacy and pharmaceutical chemistry. In 1905 he joined with the late Lowell M. Palmer to buy the business of E. R. Squibb & Sons, Dr. Squibb having died several years previously. At a time when the American market was flooded with nostrums and quack remedies, Mr. Weicker conceived the idea of an advertising campaign to the public under professional supervision to disseminate information about pharmaceutical products. He directed the campaign with the now widely known slogan "The priceless ingredient of every product is the honor and integrity of its maker," according to a statement issued at his death. The opening of the Squibb Institute for Medical Research at New Brunswick, N. J., in 1938 was the realization of a lifelong dream of Mr. Weicker, the statement said.

NORTH CAROLINA

Society News.—Dr. Virgil P. W. Sydenstricker, Augusta, Ga., will discuss pellagra before the Buncombe County Medical Society, Asheville, August 19.—Dr. John Shelton Horsley, Richmond, Va., addressed the Halifax County Medical Society, Roanoke Rapids, June 15, on cancer.—Dr. William Raney Stanford, Durham, addressed the Alamance-Caswell Counties Medical Society, Union Ridge, July 9, on "Idiopathic Ulcerative Colitis."

Plans for New School.—At a joint meeting of the trustees of the North Carolina Baptist Hospital and of Wake Forest College, July 18, contracts were let for the new Bowman Gray School of Medicine of Wake Forest College in Winston-Salem and additions to the hospital amounting to \$701,572. It is estimated that it will take a year to complete the buildings. The school will also have a fifty bed hospital which has been leased to it by the Junior League of Winston-Salem for teaching and research in psychiatry. The school will assume responsibility for the professional conduct of the child guidance clinic conducted by the league.

OHIO

Dr. Dunham Honored.—Dr. Henry Kennon Dunham, Cincinnati, who recently retired as medical director of the Hamilton County Tuberculosis Sanatorium, was honored with a dinner, June 12, given by four organizations with which he has been identified: the Christmas Seal Committee of Cincinnati and Hamilton County, of which he is president; the Cincinnati Anti-Tuberculosis League; the faculty of the University of Cincinnati College of Medicine, and the staff of the sanatorium. Dr. Stanley E. Dorst was toastmaster and the speakers were Drs. Paul P. McCain, Sanatorium, N. C.; William Muhlberg and George E. Rockwell, Cincinnati; Robert G. Paterson, Ph.D., Columbus, and Col. Clarence O. Sherrill, city manager of Cincinnati. A plaque bearing a likeness of Dr. Dunham and a tribute to his efforts has been placed in the lobby of the sanatorium.

PENNSYLVANIA

District Meeting.—The Tenth Councilor District of the Medical Society of the State of Pennsylvania held a meeting in Pittsburgh, July 17. Clinics were presented at Mercy and Western Pennsylvania hospitals and at the Falk Clinic. Speakers on the scientific program were Drs. Henry J. John, Cleveland, on "The Treatment and the Progress of Diabetic Children" and William H. Guy, Pittsburgh, "Clinical Manifestations of Syphilis with Suggestions on Treatment." Dr. Nathan A. Kopelman, New Kensington, a member of the state society's committee on industrial health, discussed "The Present Status of Industrial Medicine"; Dr. J. West Mitchell, Pittsburgh, reported the work of the commission on diabetes and Dr. John O. Bower, Philadelphia, a survey on acute appendicitis mortality by that commission. At a luncheon session Dr. Chauncey L. Palmer, Pittsburgh, discussed new state laws affecting physicians.

Philadelphia

Fellowships for Training in Criminal Psychiatry.—The joint medicolegal committee of the Philadelphia County Medical Society and the Philadelphia Bar Association announces that two fellowships for training in criminal psychiatry are open to candidates of suitable qualifications for terms of two years beginning in October. An appropriation of \$14,000 from the Commonwealth Fund of New York has made possible the installation of the "Pennsylvania Plan" for intramural training in penal psychiatry, described in *THE JOURNAL*, July 13, page 135. The plan is to be administered by a committee representing three departments of the University of Pennsylvania—the department of psychiatry, the graduate school and the law school—and the Eastern State Penitentiary. Those interested in making application for the fellowships should direct their inquiries to Dr. Philip Q. Roche, secretary of the committee on medicolegal fellowships, 255 South Seventeenth Street, Philadelphia.

TEXAS

Society News.—Dr. Ralph Bowen, Houston, addressed the Jefferson County Medical Society, Port Arthur, June 10, on "Practical Management of Allergic Problems in General Practice."—Dr. Robert L. Moore, Dallas, lectured on pediatric subjects and Dr. Daniel Truett Gandy, Houston, on diagnosis and treatment of syphilis at a meeting of the Tenth District Medical Society in Liberty, June 28.

Personal.—Dr. John W. E. H. Beck, Austin, director of local health services with the state board of health for the past three years and previously director of maternal and child welfare for one year, has resigned to return to private practice in DeKalb, it is reported.—Dr. John M. Hooper, Austin, recently succeeded Dr. James J. Croley as director of the McKinney-Collin County health unit.—Dr. James H. Stephenson has resigned as superintendent of the Jefferson Davis Hospital, Houston, according to *Hospitals*. Dr. Sidney B. Hardy is acting superintendent.—Dr. Berthold H. Estess, New Braunfels, is in charge of a new health unit for Jasper and Newton counties, with headquarters in Jasper.

WASHINGTON

State Medical Meeting at Tacoma.—The fifty-first annual meeting of the Washington State Medical Association will be held at the Winthrop Hotel, Tacoma, August 25-28, under the presidency of Dr. Warren B. Penney, Tacoma. Speakers at the scientific sessions will include:

- Dr. Kenneth K. Sherwood, Seattle, Indications and Contraindications for Gold, Vitamin C, Sulfanilamide and Thiamine Therapy for Chronic Arthritis.
- Dr. Lyle A. Greenwood, Bellingham, The Newer Drugs in the Treatment of Infections.
- Dr. Simeon T. Cantril, Seattle, Malignant Diseases of the Head and Neck.
- Dr. Milo T. Harris, Spokane, Carcinoma of the Uterus.
- Dr. Edwin G. Bannick, Seattle, Newer Procedures in the Treatment of Pneumonia.
- Dr. Cassius H. Hoffrichter, Seattle, Clinical Evaluation of Standard Protamine Zinc and Crystalline Insulin.

The annual golf tournament will be held at the Tacoma Golf and Country Club Monday, August 26. The woman's auxiliary will hold its meeting parallel with the state association, with sessions at the auditorium of the Medical Arts Building.

PUERTO RICO

Influenza Epidemic.—The department of health of Puerto Rico reports a widespread epidemic of influenza on the island, reaching its climax in July. More than 52,000 cases were reported to the department in June and July. According to a report in the *New York Times*, there were about 200 deaths. Dr. John W. Oliphant of the U. S. Public Health Service was detailed to make an epidemiologic study and Dr. Edwin H. Lennette of the International Health Division of the Rockefeller Foundation is conducting research on the virus and other aspects of the disease.

University News.—The School of Tropical Medicine of the University of Puerto Rico under the auspices of Columbia University offered its third annual vacation course in tropical medicine for undergraduate students June 18 to July 26. Three students from the University of Cincinnati College of Medicine, two from the College of Physicians and Surgeons of Columbia University, New York, and two from the Long Island College of Medicine, Brooklyn, took the course, directed by Thomas J. LeBlanc, Sc.D., Cincinnati, in conjunction with George W. Bachman, Ph.D., director of the school of tropical medicine. Laboratory and field work occupied the first week; pathology, mycology and clinical features of tropical diseases the next four weeks, and one week was devoted to demonstration in the insular health department under the direction of Dr. Garrido Morales, health commissioner.

GENERAL

American Congress of Physical Therapy.—The nineteenth annual meeting of the American Congress of Physical Therapy will be held in Cleveland, September 2-6, with headquarters at the Hotel Statler. Mornings will be devoted to instruction courses, and scientific sessions will be held in the afternoons and evenings. Among the speakers will be:

- E. K. Jett, chief engineer of the Federal Communications Commission, Washington, D. C., Radio Interference Problems Resulting from the Operation of Electric Appliances.
- Dr. Theo Drug Cosmet, drug division, U. S. Food and the New Food, Drug and
- Dr. William Bierman, New York, The Penetrative Effect of Cold.
- Dr. George W. Crile, Cleveland, Normal and Pathologic Electrophysiology.
- Dr. William F. Petersen, Chicago, The Effect of Cold, Heat and Weather on the Human Being.
- Drs. Donald L. Rose, Walter M. Simpson and Herbert Worley Kendell, Dayton, Ohio, Artificial Fever Versus Combined Fever-Chemotherapy in Gonococcal Infections Refractory to Sulfanilamide.
- Dr. Edgar V. Allen, Rochester, Minn., Treatment of Diseases of the Peripheral Blood Vessels.
- Dr. Charles E. Irwin, Warm Springs, Ga., Mechanical Aids for the Severely Handicapped Poliomyelitis Patient.
- Dr. Frank H. Krusen, Rochester, Minn., Present Status of Ultraviolet Irradiation.
- Dr. Richard E. Reilly, Minneapolis, Histamine Iontophoresis in Chronic Arthritis.

Included on the program of the section on eye, ear, nose and throat is a symposium on audiometry and hearing aids to be presented by Howard A. Carter, B.S. in M.E., secretary, Council on Physical Therapy, American Medical Association, Chicago; Drs. Charles E. Kinney, Cleveland, and G. Henry Mundt, Chicago.

Fake Insurance Salesman.—A Louisiana physician reports that a man posing as a "special agent" of the Mutual Benefit Health and Accident Insurance Company, Omaha, is visiting physicians who already have policies with this firm and selling them additional insurance. In reply to a complaint, the com-

pany informed the physician that the salesman described was not in its employ at this time and that other reports of his activities had been received. He appears to be operating in the Gulf Coast states. In the case reported he used the name "Amos L. Rogers." He appeared to be from 35 to 40 years old, weighed about 200 pounds and was about 6 feet tall.

Grants for Cancer Research.—The National Advisory Cancer Council at a meeting, June 25, at the National Cancer Institute in Bethesda, Md., awarded grants for research on cancer. The grants were: Washington University School of Medicine, St. Louis, \$16,000; Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, \$3,300; Barnard Free Skin and Cancer Hospital, St. Louis, \$5,000; University of California Medical School, San Francisco, \$5,000, and American College of Surgeons, Chicago, \$5,900. Among reports presented at the meeting was a special one on protection of personnel working in cancer clinics against injury from exposure to radium, x-rays and neutrons, by Carl Voegtlin, Ph.D., chief of the cancer institute.

LATIN AMERICA

Society News.—The fourth Pan American Conference of Directors of Public Health will be held in Rio de Janeiro, Brazil, in 1942 and the fourth Pan American Conference of Leprology also in Rio de Janeiro in 1945.—Dr. Eduardo de Moraes was recently elected president of the Medical Society of Bahia, Brazil; Drs. Eduardo Vidal da Cunha and Pedro Ferreira, vice presidents, and Jose de Figueiredo, general secretary.—The eighth congress of the Pan American Medical Association will be held in Buenos Aires in 1941 under the presidency of Dr. Jose Arce, Buenos Aires. Previous congresses have been in Habana, Panama, Mexico, Dallas, Antillas Menores, Rio de Janeiro and São Paulo and again in Habana.—The International College of Surgeons will hold its next meeting in Mexico City, Aug. 10-13, 1941, according to an announcement in *Medicina* (Mexico).

CORRECTION

Acetanilid Instead of Acetophenetidin.—In the twelfth line of the editorial entitled "Double Barreled Self Medication" in *THE JOURNAL*, August 3, page 387, the word "acetophenetidin" should be "acetanilid."

Government Services

War Department Needs Pathologist and Veterinarian

The U. S. Civil Service Commission announces open competitive examinations for a pathologist (medical) and a veterinarian for the Chemical Warfare Service, War Department, Edgewood Arsenal, Md. The duties of the pathologist will be to examine specimens of pathologic tissue, to interpret and determine gross and microscopic changes produced in men and animals by chemical warfare agents and other toxic agents and to examine and interpret the physical effects of preventive and therapeutic measures for these changes. The veterinarian's duties will be to determine toxic effects as shown from gross pathologic changes induced by various agents in animals, to interpret the transfer of data obtained from animal experiments to man, to supervise the health and treatment of experimental animals and to perform related duties. Competitors will not be required to report for examination at any place but will be rated on the extent of their education, on the extent and quality of their experience relevant to the duties of the position applied for and on their fitness, on a scale of 100, such ratings being based on competitors' sworn statements in their applications and on corroborative evidence. For pathologist, applicants must have completed a four year college course with major study in biology or chemistry or must have graduated from a recognized medical school and must have had appropriate experience in pathology, either human or animal. For veterinarian, applicants must have a degree in veterinary medicine or meat inspection or disease control work. Detailed requirements and application forms may be obtained from the secretary of the board of civil service examiners at any first or second class postoffice or from the U. S. Civil Service Commission, Washington, D. C. Applications must be on file in the commission's Washington office not later than September 9, if received from states east of Colorado, and not later than September 12, if received from Colorado and states westward.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 20, 1940.

A Revolutionary Step in Diet: The Fortification of Bread

In the House of Commons Mr. Boothby, secretary to the Ministry of Food, stated that 90 per cent of our food imports were purchased by the government generally at little over pre-war prices but that there was a substantial increase in the cost of transportation. Adequate supplies of meat for the masses at reasonable prices would be secured. Scientists said that meat did not have great advantages dietetically. That might be, but it had a psychologic value. It made people happy. When the threatened attack on these islands in the next few months was defeated we could increase the distribution of tea and sugar and perhaps fats during the winter months. To keep down the cost of living the government was subsidizing foods—bread and flour to the weekly rate of \$2,975,000, home produced meat \$1,575,000, bacon \$500,000. In addition the milk scheme of selling below cost to poor families cost \$37,500,000 per annum. We had stocks of food sufficient for many months in the unlikely event of heavy losses at sea.

THE FORTIFICATION OF BREAD

The minister then dealt with bread, about which there has been much controversy. He said that nutritional experts stressed the importance of wholemeal bread as compared with white bread. One reason why the manufacture of white flour had not been suspended was that most consumers preferred white bread. For security the government had greatly increased not only our stocks of wheat but also the proportion held in the form of flour. The keeping qualities of white were greater than those of wholemeal flour and therefore our reserve was kept in that form. To overcome the main objection to white flour—its deficiency in vitamins—the government intended to fortify it by adding vitamin B₁ and also to introduce a small quantity of calcium salt. Some months must elapse before sufficient vitamin B₁ was available. The public would then have the choice of fortified white bread or wholemeal bread at the same price. This was a revolutionary step and in conjunction with the milk scheme would lay the foundation of a nutritional policy. The decision to fortify white bread was taken after a report of the scientific committee under the chairmanship of Sir William Bragg (physicist and president of the Royal Society) had been received. It was a satisfaction that the government's import policy had been endorsed by the committee, but he hoped that this would not go to the heads of the scientists. The government had to consider the human man, who might get all the vitamins he required from a diet of vegetables, wholemeal bread, milk and cheese but would be most unhappy. He once attended an "Oslo meal" and came away full of vitamins, but that did not prevent a disturbed night. They were not cranks at the Ministry of Food. In war, food was the most fundamental and the most decisive factor.

Detection of Tuberculosis in Recruits

A medical advisory committee under the chairmanship of Lord Horder, appointed to report on methods of detecting early tuberculosis in men called up for military service, has made the following recommendations: 1. Every recruit at his examination by the medical board should be required to sign a declaration indicating whether or not he has suffered from tuberculosis. 2. District medical officers should be required to furnish a notification of every man of military age whose name appears on the registers kept under the public health (tuberculosis) regulations, so that this notification may be presented when he

attends for examination. 3. The attention of medical board should be directed to the value of x-ray examination of the chest in the detection of early cases of pulmonary tuberculosis and they should be urged to use it in the case of recruits whose medical history or chest condition indicates even a remote possibility of the disease. 4. Medical boards should be advised to consider this special examination in cases of general ill health without definite clinical signs and also in those cases of effort syndrome in which there is no definite indication of psychic or cardiac cause. The committee inquired into the possibility of examining radiologically the chests of all recruits. For large numbers of men this could be done only by miniature radiography. While admitting that the method represents an ideal to be aimed at, the committee says that the necessary apparatus and a sufficient number of expert examiners would not be available for some months. The method is therefore impracticable at present. But the Admiralty and Air Ministry are about to make a trial of miniature radiography, and the committee await the results with interest.

Proposed National Scheme of Fracture Clinics

Since the war of 1914-1918, in which the late Sir Robert Jones was given direction of orthopedic surgery in the military hospitals, increased attention has been given to the treatment of fractures. In a memorandum to the Ministry of Health the British Hospitals Association proposes that the government set up a special committee to promote a fracture scheme in conjunction with the hospitals. The state is asked to make an initial grant of \$1,250,000 toward the cost, and the association would draw up a plan to provide the nucleus of an organization and suggest the personnel. The government in 1936 set up a rehabilitation committee to consider the facilities available for the special treatment which cases of fracture require. In 1939 this body recommended a scheme for setting up fracture services throughout the country and made proposals which it hoped would enable the voluntary hospitals to finance them. The probability of heavy casualties is now thought to call for the intervention of the state in setting up such clinics. But it is held that it would be a mistake for the state to set up its own clinics otherwise than in cooperation with the voluntary hospitals, which treat 90 per cent of fractures of civil life. All that is required is reorganization and extension of existing services. Their fracture departments covering surgical treatment, physical therapy and remedial exercises would be placed under the control of a specialist with a team of assistants, radiographers and nurses. Special equipment would have to be provided.

It is calculated that the cost of setting up the additional fracture services at existing hospitals would be about \$10 a case. This would not be the total cost of treating the fractures but the cost of improvement of the present services. The number of fractures treated annually at the hospitals is about 200,000 in peace time; in war time an increase to 500,000 is to be expected. Only eighty-six hospitals in Great Britain apart from twenty-four orthopedic hospitals have fully organized fracture services. Probably only 100,000 cases annually can obtain adequate treatment in fracture services at present. The immediate object is the establishment of a fracture service in each area. Other needs are rehabilitation or vocational training centers and settlements where those too incapacitated to resume their ordinary work can be housed and taught crafts.

The Bureau of Human Heredity

More than three years ago a Bureau of Human Heredity was established in London for the purpose of helping workers in human genetics. The chairman is Prof. R. Ruggles Gates, F.R.S. It now has a collection of books and reprints amounting to more than 3,000, which is indexed by a system of cross reference running to many thousands of cards, so that a worker

can easily turn up any point. Specialist inquirers can be quickly supplied with bibliographic references. The work of the bureau has automatically brought into being a comparative definition of terms used variously by different schools. A series of more than 7,000 terms occurring in genetic literature has been arranged in a synonym index, which could serve as a basis for a lexicon of terminology.

The work of the bureau has indicated the need for several investigations and has pointed the way to them. One is a complete collection and analysis of all material on genetics in relation to cancer, and the same holds for tuberculosis. In view of their importance these two surveys have begun. Some suggested investigations have special reference to the war. Among these are allergic conditions in connection with prophylactic inoculation of the fighting forces, neuroses under war strain, physiologic constitution in the choice of air pilots and constitutional factors in wound therapy.

BUENOS AIRES

(From Our Regular Correspondent)

July 5, 1940.

Regulations on the Appointment of Hospital Physicians

The selection of the medical personnel of municipal hospitals in Buenos Aires has now been regulated. The title of hospital physician will be accorded only to physicians of Argentine birth who have had experience in recognized hospitals. The order of advancement is as follows: assistant physician, associate physician, hospital physician, resident physician, head of hospital service and director of the hospital. Appointments are based on competitive examinations. Hospitals are divided into medical clinics, surgical clinics and the specialties, including the departments of orthopedic surgery and traumatology, neurologic surgery, child surgery, infectious diseases, tuberculosis, gynecology, ophthalmology, otorhinolaryngology, neurology, psychiatry, diseases of nutrition, diseases of the blood, dermatology and syphilology, proctology, radiology and physical therapy. The laboratories comprise laboratories for clinical and microbiologic analysis, for pathologic anatomy, hematologic laboratories and a central laboratory for clinical and microbiologic analysis and hygiene. The order of advancement is the same here as for the hospitals; the title, however, in each case indicates the connection with a laboratory. Physicians are assigned on the basis of one hospital physician to every twenty beds, one associate physician to ten beds or fewer and three assistant physicians to each associate physician. The central laboratories and those of the radiology and physical therapy divisions each have a head and in addition two hospital physicians, three associate physicians and five assistant physicians. The qualifications for the various hospital service orders have been worked out in detail. An examining board, consisting of the director of the hospital and two divisional heads, chosen by lot, pass on the training, degree and scientific contributions of the applicant. An associate is required to have had five years' experience as assistant in the specialty for which he is an applicant. The full hospital physician must have served five years as associate and must also submit to an oral examination that embraces both theory and practice of medicine. The examining board consists of five service heads. Only associate physicians of general surgery are admitted as candidates for the position of resident physician. They are also examined in operative technique. Appointments are valid for three years and may be renewed for two successive periods. They permit subsequent hospital connection as associates. A vacancy in the headship of a ward is open first of all to heads of wards of other hospitals. The examining board consists of the heads of five other wards who have served at least five years. It passes *inter alia* on the applicant's ability to organize the hospital and polyclinic service, the conduct of hospital records, supervision of the rationalized

nutritional needs of the patients, and so on. Any remaining vacancy is open to hospital physicians who have served more than five years in the same specialty. An examination is required covering a clinical case determined by lot twenty-four hours previously. If the vacancy is in the field of surgery, the examining board observes the applicant at work. The appointment is valid for ten years and may be renewed for five years more. The retiring age is 65. Hospital directors are selected on the same plan. If a vacancy remains, heads of wards with a ten year service are eligible.

Physicians who change their specialty are subject to certain regulations. They are appointed on competitive examination and are required to serve five years in the new specialty. The heads of the wards elect a clinical head from among the full or associate physicians, as the case may be. He serves for two years and is eligible for reelection. The head of the polyclinic connected with the hospital must have the rank either of medical physician or of clinical head. Physicians may also be assigned on honorary appointments.

Postgraduate Lectures

The Asociación médica Argentina has organized on a more extensive plan the lecture courses offered last year. Sessions meet in the evening and are held monthly. A definite subject chosen for each evening service is discussed by experienced clinicians. In the first session recently held under the chairmanship of Prof. Carlos Mainini, its president, the sulfonamides were discussed. Prof. E. Hug of Rosario introduced the subject with a pharmacologic lecture. Subjects for future discussion include hypertrophy of the prostate, erythremia, endocrine preparations in ovarian disturbances, shock and collapse therapy in pulmonary tuberculosis. Similar lectures are given in the national polyclinic for diseases of the digestive apparatus.

Personals

The Liga Argentina contra el reumatismo, under the presidency of Dr. Aníbal Ruiz Moreno, conferred honorary membership on Drs. Walter Bauer, Ralph Boots, Russel L. Cecil, Martin Henry Dawson, Richard Freyberg, Marshall Hall, William Kerr, J. Albert Key and Loring T. Swaim.

Under the auspices of the Argentine Radiologic Society (Sociedad Argentina de Radiología) the first radiologic congress will be held in Argentina September 23-24.

Prof. Angel H. Roffo, well known Argentine cancerologist, was made an honorary doctor by the University of Guatemala.

Prof. Evandro Chagas gave several lectures on visceral leishmaniasis in the institute of infectious diseases of the Faculty of Medicine of Buenos Aires.

Marriages

BEN ROLAND WILTBERGER, Detroit, to Miss Helen Elizabeth Slack of Columbus, Ohio, June 10.

DONALD DWIGHT COOPER, Towson, Md., to Miss Margaret Matthews of Roanoke, Va., July 15.

JACK CHESNEY, Knoxville, Tenn., to Miss Helen Wallace McColl of Bennettsville, S. C., July 20.

JOSEPH AUGUSTINE LUNDY, Oxford, Mass., to Miss Maude Marion McKewen of Worcester, July 17.

JAMES THOMAS GREEN to Miss Mary Wright Shand, both of Columbia, S. C., June 4.

NORMAN OLIN EADDY to Miss Dorothy Compton, both of Sumter, S. C., May 29.

HARRY GAMBILL STANDAUGH, Ashland, Ky., to Mrs. Cleo Eubank Ehrlich, June 8.

ARTHUR A. DAVIDMAN, Rocky Mount, Va., to Miss Tamara Zanoff in Baltimore, July 7.

HENRY S. CHRISTIAN, Three Notch, Ala., to Miss Mac Hall in Midway, July 20.

Deaths

Sigard Adolphus Knopf ☉ New York; Bellevue Hospital Medical College, New York, 1888; Université de Paris Faculté de Médecine, France, 1895; professor of medicine, New York Post-Graduate Medical School, from 1908 to 1920; honorary director of the Gaylord Farm Sanatorium, Wallingford, Conn.; visiting physician to the Riverside Hospital from 1904 to 1923; consulting physician to Sanatorium Gabriels, Gabriels, N. Y., West Side Hospital, Scranton, Pa., and of the Bruchesi Institute, Montreal; a founder of the National Tuberculosis Association, and the New York Tuberculosis and Health Association; honorary member of the American Association for Thoracic Surgery; a government delegate to the International Prison Congress in Budapest and the International Tuberculosis Congress in Paris; vice president of section V of Tuberculosis Congress in Washington in 1908; delegate to the International Congress on School Hygiene in Buffalo in 1913; in 1898 received the Alvarenga Prize awarded by the College of Physicians of Philadelphia; in 1932 represented the United States at the congress of the International Union Against Tuberculosis at The Hague; served during the World War; author of "A History of the National Tuberculosis Association," and of "Heart Disease and Tuberculosis," published in 1936; aged 82; died, July 15, in the Mount Sinai Hospital.

Frederick Gault Finley, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1885; emeritus professor of medicine and at one time dean at his alma mater; past president of the Montreal Medico-Chirurgical Society; member of the Association of American Physicians; served with the Canadian Army Medical Corps during the World War; was connected for many years with the Montreal General Hospital of which he was consultant as well as of the Royal Victoria and the Children's Memorial hospitals; was chairman of the medical board of the Jewish General Hospital; aged 78; died, July 6.

Vaughan Quaine Bonham, Fayette, Mo.; University of Nashville (Tenn.) Medical Department, 1877; Vanderbilt University School of Medicine, Nashville, Tenn., 1883; member of the Missouri State Medical Association; past president of the Missouri Public Health Association; in 1910 was appointed registrar of birth and death certificates for Missouri; at one time member of the board of managers of the State Hospital, Number 1, Fulton, Mo.; aged 83; died, June 23, in the Lee Hospital of a fractured hip and chronic myocarditis.

Robert Roy Hampton ☉ Salt Lake City; College of Physicians and Surgeons, School of Medicine of the University of Illinois, Chicago, 1900; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otolological Society, and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; on the staff of St. Mark's Hospital; aged 65; died, July 12, of coronary occlusion.

P. Calixte Dagneau, Quebec, Que., Canada; M.B., Laval University Faculty of Medicine, Quebec, 1899, and M.D., 1901; dean and professor of surgical pathology, ethics and clinical surgery at his alma mater; past president of the College of Physicians and Surgeons of the Province of Quebec; was surgeon at the Hotel-Dieu from 1914 to 1927, when he became chief surgeon at St. Sacrament Hospital; was decorated by France and Italy; aged 63; died, June 28.

Frederick A. Speik ☉ Los Angeles; Rush Medical College, Chicago, 1907; fellow of the American College of Physicians; at one time professor of medicine at the College of Physicians and Surgeons, medical department of the University of Southern California; formerly chief of the department of medicine of the County Hospital; on the staff of the Collis P. and Howard Huntington Memorial Hospital, Pasadena; aged 58; hanged himself, June 30.

George Livingston Hays, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1895; professor of clinical surgery at the University of Pittsburgh School of Medicine; fellow of the American College of Surgeons; member of the Medical Society of the State of Pennsylvania; surgeon to the Mercy Hospital; aged 70; died, June 22.

Walter Wendell Fray ☉ Rochester, N. Y.; Harvard Medical School, Boston, 1922; assistant professor of radiology at the University of Rochester School of Medicine and Dentistry; member of the American Roentgen Ray Society and the American College of Radiology; on the staff of the Strong Memorial Hospital; aged 47; died, July 10, of leukemia.

John Harolde Turner ☉ Houston, Texas; University of Texas School of Medicine, Galveston, 1919; member of the American Urological Association; fellow of the American College of Surgeons; visiting urologist to the Baptist and Jefferson Davis hospitals; visiting urologist and assistant director of the Turner Institute; aged 45; died, June 1.

George Stuart Bower, Galesburg, Ill.; Northwestern University Medical School, Chicago, 1894; member of the Illinois State Medical Society; past president and secretary of the Knox County Medical Society; for many years county coroner; on the staff of the Galesburg Cottage Hospital; aged 71; died, July 14, of coronary thrombosis and hypertension.

Robert Woods Noble, Temple, Texas; Memphis (Tenn.) Hospital Medical College, 1887; member of the State Medical Association of Texas; formerly a member of the state board of health and for many years health officer of Temple; on the staff of the King's Daughters' Clinic and Hospital; aged 76; died, June 20, of acute coronary thrombosis.

Joseph Dayton Condit ☉ Pasadena, Calif.; Columbia University College of Physicians and Surgeons, New York, 1901; fellow of the American College of Physicians; served during the World War; on the staffs of the Huntington Memorial and St. Luke's hospitals; aged 63; died, July 5, of carcinoma of the stomach with peritoneal metastases.

George Driver Bragaw, Augusta, Ga.; Georgetown University School of Medicine, Washington, D. C., 1911; member of the American Psychiatric Association; on the staff of the Veterans Administration Facility; aged 54; died, July 1, of coronary thrombosis and arteriosclerosis following a laminectomy.

Ira N. Pickett, Odell, Neb.; Indiana Medical College, Indianapolis, 1878; member of the House of Delegates of the American Medical Association in 1905-1906; member and past president of the Nebraska State Medical Association; aged 87; died, June 18, of myocarditis and cerebral hemorrhage.

Cecil Edward Ross, Erie, Pa.; Western Reserve University School of Medicine, Cleveland, 1931; member of the Medical Society of the State of Pennsylvania; member of the board of directors of the Erie County Tuberculosis Hospital; on the staff of St. Vincent's Hospital; aged 37; died, June 26.

John Irwin Zerbe ☉ Franklin, Pa.; Medico-Chirurgical College of Philadelphia, 1907; county coroner; past president and secretary of the Venango County Medical Society; served during the World War; on the staff of the Franklin Hospital; aged 61; died, June 16, of coronary thrombosis.

James Stewart Archibald ☉ Danville, Ill.; St. Louis University School of Medicine, 1908; served during the World War; on the staff of St. Elizabeth's Hospital; formerly on the staff of the Decatur and Macon County Hospital, Decatur; aged 57; died, July 17, of coronary thrombosis.

Robert Francis Jones ☉ Medical Inspector Commander, U. S. Navy, retired, Savannah, Ga.; University of Virginia Department of Medicine, Charlottesville, 1909; entered the navy in 1911 and retired in 1937 for incapacity resulting from an incident of service; aged 54; died, July 4.

James G. Muir, Milford, Neb.; Lincoln Medical College of Cotner University, 1898; member of the Nebraska State Medical Association; served during the World War; aged 62; died, June 29, in the Veterans Administration Facility, Lincoln, of coronary arteriosclerotic heart disease.

James Stephen Maher, New Haven, Conn.; Yale University School of Medicine, New Haven, 1896; member of the Connecticut State Medical Society; past president of the city board of health; for many years on the staff of the Hospital of St. Raphael; aged 68; died, June 8.

John James Collins ☉ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1898; served during the World War; aged 68; for many years on the staff of St. Mary's Hospital, where he died, July 8, of hypertensive heart disease and chronic nephritis.

John R. Gillette, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1892; formerly member of the state legislature and member of the county and city school boards; aged 73; died, July 15, at his summer home in Yardley, Pa., of coronary thrombosis.

Robert Eugene Golden, Walla Walla, Wash.; University of Oregon Medical School, Portland, 1904; member of the Washington State Medical Association and the Pacific Coast Oto-Ophthalmological Society; veteran of the Spanish-American War; aged 64; died, June 30.

Edward Clayton Davis, Philadelphia; Temple University School of Medicine, Philadelphia, 1910; member of the Medical Society of the State of Pennsylvania; formerly assistant professor of bacteriology at his alma mater; aged 63; died, June 10, in the Northeastern Hospital.

Charles Fallis Hewins, Oakland, Calif.; Long Island College Hospital, Brooklyn, 1882; University of Pennsylvania Department of Medicine, Philadelphia, 1890; aged 83; died, June 27, in the Providence Hospital of bronchopneumonia and coronary occlusion.

John Henry Charles Willoughby, Dundas, Ont., Canada; Victoria University Medical Department, Coburg, 1884; at one time postmaster in Saskatoon and member of the board of trustees of the school board; formerly mayor of Regina; aged 78; died, May 22.

John Thomas Corr, Racine, Wis.; Rush Medical College, Chicago, 1896; member of the State Medical Society of Wisconsin; served during the World War; aged 70; died, June 5, in St. Mary's Hospital of carcinoma of the colon and cardiac decompensation.

Robert Lee Yeager ☉ Mineral Wells, Texas; University of Texas School of Medicine, Galveston, 1898; past president and secretary of the Palo Pinto County Medical Society; on the staff of the Nazareth Hospital; aged 68; died, June 19, of septicemia.

Jennie Sharp Sharp, Camden, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1895; member of the Medical Society of New Jersey; formerly member of the board of education; aged 67; died, June 21, in Haddonfield.

Homer Sylvester, Madison, Wis.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; served during the World War; on the staff of the Mendota (Wis.) State Hospital; aged 71; died, June 11, in a local hospital.

Le Grand Spaulding, Kennewick, Wash.; California Medical College, San Francisco, 1902; College of Physicians and Surgeons of San Francisco, 1906; member of the Washington State Medical Association; aged 65; died in June.

Buford B. Jones, Metter, Ga.; University of Georgia Medical Department, Augusta, 1904; member of the Medical Association of Georgia; for many years chairman of the board of education and mayor; aged 66; died, June 26.

William Turner Ray, Charlotte, N. C.; University of Maryland School of Medicine, Baltimore, 1934; member of the Medical Society of the State of North Carolina; police surgeon; aged 37; died, June 16, of heart disease.

August C. Huebner, Onaway, Mich.; Michigan College of Medicine and Surgery, Detroit, 1896; member of the Michigan State Medical Society; aged 67; died, July 1, in the Blodgett Memorial Hospital, Grand Rapids.

John T. Henderson, South Euclid, Ohio; Cleveland Homeopathic Medical College, 1900; aged 75; died, July 10, in the Huron Road Hospital, East Cleveland, of injuries received in an automobile accident.

Earl G. Grover ☉ Ashland, Ohio; University of Louisville (Ky.) School of Medicine, 1921; aged 46; died, July 2, in the Hurley Hospital, Flint, Mich., following an operation for gangrenous cholecystitis.

Russell Smith Clymer, Andrews, Ind.; Indiana University School of Medicine, Indianapolis, 1928; aged 38; died, July 15, at the Methodist Hospital, Indianapolis, of injuries received in an automobile accident.

Edward Carroll James Jr., White Plains, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1925; member of the Medical Society of the State of New York; aged 40; died, June 4.

Onie Ann Barrett, Wakeman, Ohio; University of Wooster Medical Department, Cleveland, 1893; Cleveland Medical College, 1893; aged 68; died, July 4, in the Norwalk Memorial Hospital, Norwalk.

William Frank Edmonds ☉ Seattle; State University of Iowa College of Medicine, Iowa City, 1904; aged 64; died, July 3, of injuries received in an automobile accident near Twin Falls, Idaho.

J. Roma Tremblay, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1897; aged 68; was found dead, June 23.

William Asher La Ross, McDonald, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; past president of the Washington County Medical Society; aged 72; died, June 16.

William L. McBrien, Staunton, Ill.; St. Louis College of Physicians and Surgeons, 1898; on the staff of St. Francis Hospital, Litchfield; aged 75; died, July 10, of carcinoma of the bladder.

D. N. Twyman, Appomattox, Va.; Medical College of Virginia, Richmond, 1905; member of the Medical Society of Virginia; aged 63; died, June 25, of malignancy of the esophagus.

Samuel Warren De Long, Tingley, Iowa; Ensworth Medical College, St. Joseph, Mo., 1907; aged 76; died, June 9, in the Greater Community Hospital, Creston, of heart disease.

Frank Beaty Wilson, Winter Haven, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; served during the World War; aged 61; died, June 26, of pneumonia.

John Leonard Jennings Sr., Danville, Va.; Southern Homeopathic Medical College, Baltimore, 1900; aged 64; died, July 7, in the Memorial Hospital of coronary occlusion.

Burrell Brade Liles, Houston, Texas; University of Louisville (Ky.) Medical Department, 1910; member of the State Medical Association of Texas; aged 63; died, June 28.

Bernard D. Verret ☉ Rolla, N. D.; M.B., Laval University Faculty of Medicine, Quebec, 1898, and M.D., 1900; formerly county health officer; aged 64; died, May 26.

Charles Clinton Morris ☉ Paducah, Ky.; University of Louisville Medical Department, 1910; served during the World War; aged 60; died, June 30, of coronary thrombosis.

Simon Peter Earnest ☉ Delmont, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1890; for many years member of the board of education; aged 75; died, July 11.

Merle Barbee, Torrington, Wyo.; St. Louis College of Physicians and Surgeons, 1906; served during the World War; aged 60; died, July 10, of cirrhosis of the liver.

Robert Emmet Owen, St. Louis; Marion-Sims College of Medicine, St. Louis, 1901; served during the World War; aged 62; died, June 22, of coronary occlusion.

Edwin J. West, Easton, Pa.; Hahnemann Medical College and Hospital, Chicago, 1891; St. Louis College of Physicians and Surgeons, 1901; aged 80; died, June 16.

Wilbur Jay Sawyer, Cleveland; Cleveland-Pulte Medical College, 1913; aged 53; for many years on the staff of the Lutheran Hospital, where he died, July 14.

Jesse B. McKinney, Caruthersville, Mo.; Barnes Medical College, St. Louis, 1907; aged 56; died, June 23, in the Methodist Hospital, Memphis, Tenn., of heart disease.

Jefferson D. Campbell, Greeneville, Tenn.; University of Louisville (Ky.) Medical Department, 1890; aged 78; died, July 10, of carcinoma of the rectum.

Milton Girard Edmonds, Mobile, Ala.; Howard University College of Medicine, Washington, D. C., 1927; aged 38; was found dead, July 1, of myocarditis.

Jesse Edward Rayne, Elizabeth, N. J.; University of Louisville (Ky.) Medical Department, 1906; aged 60; died, June 28, of coronary thrombosis.

Felix Joseph Lownik ☉ Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1915; aged 46; died, July 11, of cerebral hemorrhage.

Forest Monroe Reid, Philadelphia; Howard University College of Medicine, Washington, D. C., 1920; aged 52; died, June 25, of coronary occlusion.

George B. Parkhill, Crosbyton, Texas; Memphis (Tenn.) Hospital Medical College, 1904; aged 62; died, June 29, of a self-inflicted bullet wound.

Norman Edwin Mighell, Pullman, Wash.; Rush Medical College, Chicago, 1884; aged 77; died, June 25, of arteriosclerosis and coronary occlusion.

Frederick Andrew Mendlein ☉ Buffalo; University of Buffalo School of Medicine, 1897; aged 69; died, July 12, in the Deaconess Hospital.

Gerald A. Sparling, Kirksville, Mo.; American Medical College, St. Louis, 1880; aged 84; died, June 23, of bronchopneumonia.

Royal Warren Bemis, Philadelphia; Jefferson Medical College of Philadelphia, 1892; aged 72; died, July 8, of coronary occlusion.

Henry L. McGee, Milton, Tenn. (licensed in Tennessee in 1903); aged 68; died, June 20.

Bureau of Investigation

STUFF FROM THE SEA

Kelp Is Seaweed—Not a Cure-All

The issuance of a Post Office fraud order against a concern variously known as Dr. Fack's Institute and Dr. Fack's Health Institute, at San Antonio, Texas, and its officers and agents, brings into the limelight the chief promoter, one Hugo R. Fack, and his activities in the field of quackery.

Hugo R. Fack first came to the attention of the American Medical Association through the May 1928 issue of a health fad magazine, "How to Live for Health and Strength." This carried Fack's "Authorized Translation from the German" of an article, "The Problem of Rejuvenation Solved," attributed to "G. Von Gogern, Traveler, Lecturer, Author." The article was largely a puff for an alleged rejuvenator from the orient (via Germany), known as "Lukutate." This nostrum for a time was played up in the United States and was dealt with under that

title in THE JOURNAL, Jan. 25, 1930, and again in the issue of April 23, 1932, under the subject "Dur-Inda, or Lukutate Redivivus" as the product had acquired a new name.

Next, Fack was observed advertising his booklet "The Necessity of Saving the Tonsils and Their Natural Non-Surgical Treatment." This appeared in a 1929 issue (month not given) of "McFerrin's Health Bulletin," put out by the food faddist Charles B. McFerrin, of Orlando, Fla., where Fack also held forth, operating, it was reported, an outfit first known as the "Natural Healing Institute" and later called the "Vitae Health Products Co." In the same year (1929) it was said that he moved this concern to San Antonio, Texas, and advertised the "Tonsalvator," a device for treating enlarged and diseased tonsils.

In 1933 a letter was sent out on a printed letterhead bearing the imposing title "Dr. Fack's Institute & Sanitorium—Naturopathic Clinic and Rest Home." There was also a subtitle, "Scientific Diet and

Drugless Methods." Also shown were the names "Hugo R. Fack, N.D., D.Orth. Ph.D.," "Emma D. Fack, N.D., D.Orth.," and "J. D. Armstrong, M.D." The American Medical Association's exhaustive files revealed no record of any J. D. Armstrong as a doctor of medicine licensed in Texas. When a form was addressed to this name in care of the Fack outfit, asking for Armstrong's medical credentials, it was returned unsigned, with the simple typewritten notation "deceased."

The Fack letter played up not only the "Tonsalvator" but also something called "Sepdelenopathy" and described as "a treatment for the elimination of toxic materials." An accompanying circular offered various nostrums by Fack, including "Fruitellax," for constipation, "Piscin—the Superior Substitute of Codliver Oil in Powderform," and "Vitae Herbs," an apparent cure-all "biologically blended after the ancient significant doctrine." (How often the faddists play up the mystical!) Finally there was "Dr. Fack's Femi-Sanax, an instrument of far-reaching therapeutic results in feminine sufferings."

In recent years Fack also has been putting out "Vegesan," described as "the essentially supplementary food in fine powder form, supplying to the system all of the needed organic materials and vitamins." Also it was claimed that "Vegesan is a pure

vegetable food, which grows in certain Southern Oceanic regions. The choicest leaves of plants are selected, washed, dried in a current of air outdoors (not in withering, i. e., Vitamin destroying sun rays), then ground into fine powder form which makes complete assimilation by the human system easy and highly economical in its use while revealing its relish taste." The advertising played up a string of testimonials from so-called doctors but, as their full names and addresses were not divulged, there was no means of identifying them.

After the Post Office Department had looked into Fack's activities it called on him to show cause why a fraud order should not be issued against him. He replied with a written answer denying the charges. He also failed to appear at a second hearing of the case and did not even send a representative. Soon afterward he sent the Post Office Department a second communication and requested permission to discontinue and abandon voluntarily the enterprise in question. Accordingly he was sent a form for making affidavit of his promise but instead of duly executing and filing it he sent in a series of further communications setting forth the alleged value of his Vegesan, which he had sold through the mails.

The Post Office memorandum by virtue of which the (October 1939) mails were closed to this scheme brought out that Fack claimed that he had obtained certain medical training at Heidelberg and Leipzig, Germany, and had been licensed to practice "naturopathy" in Florida in 1927. The memorandum pointed out that Fack had sold his Vegesan through the mails under the false and fraudulent representations that, regardless of any disease or affection involved, Vegesan would restore those who took it to permanent health: that it would prevent or cure goiter, anemia, rickets, obesity, pyorrhea, constipation, "auto-intoxication," catarrh, deafness, "old age," any disease of the heart or liver, insanity, insomnia, diabetes, sterility, and a few other things!

Fack was said to have obtained the material for Vegesan in wholesale quantities from a Los Angeles concern and to have repackaged it in his home. According to the Post Office Inspector in the case Fack, when first interviewed, stated that he did not know the composition. Government chemists reported that a microscopic examination showed it to be composed entirely of dry, finely ground seaweed, or kelp. It was brought out at the hearing that, contrary to Fack's representations that Vegesan was a rich and abundant source of all organic minerals and vitamins, the only substances it contained in therapeutic quantities were iodine and vitamin A, and that any other minerals and vitamins present were too inconsiderable in amount to have any medicinal value.

The government presented expert medical evidence that Vegesan would not overcome obesity, gland disturbances, slow and defective sexual development, toxemia, insanity, tooth decay and the rest of Fack's category and that these conditions require painstaking individual diagnosis with a view to finding the underlying factors responsible for the disease and the employment of personalized procedure adapted to the patient's needs. It was further shown that while Vegesan might be mildly laxative it would not "normalize" alimentation as Fack claimed but, on the contrary, would interfere with the appetite and digestion and produce undesirable intestinal symptoms and even aggravate disorders of the gastrointestinal tract such as ulcers, appendicitis and colitis, and also involve grave and perhaps fatal consequences when substituted for scientific treatment of heart, kidney, arterial and other serious diseases.

The evidence also showed that the iodine present in Vegesan, while it might be of some value in simple goiter, could not remedy goiter of the exophthalmic or adenomatous types, overcome cretinism or provide safe or proper treatment for disorders of the thyroid gland which may have caused these conditions.

Fack apparently set himself up as an authority on diet, as he sent out advice on the use of foods in connection with Vegesan. These instructions urged the purchase of his "De-Tox-San" and "Sepdelen."

Here, then, is another of the countless "patent medicines," many of them based on kelp, which the public is importuned to buy on the ground that they supply minerals and vitamins which, according to the food faddists and nostrum exploiters, are lacking in the ordinary diet. Of course they don't do anything of the kind.

EVALUATION OF THE PROSTIGMINE TEST FOR EARLY PREGNANCY

To the Editor:—Soskin, Wachtel and Hechter reported in THE JOURNAL (May 25, p. 2090) on the value of prostigmine in inducing menstruation in women who had missed their regular menstrual cycle. These authors stress the role that hyperemia may play in menstruation and attempt to correlate the parasympathetic nervous system with it. They write:

This relationship of the nervous system to uterine hyperemia might readily account for the well known influence of mental, emotional and physical strain on the menstrual history of women. It thus appeared possible that cases of delayed menstruation, now generally ascribed to temporary endocrine dysfunctions, might in fact occur despite normal hormone secretion and be due to abnormally decreased vascular responsiveness. It therefore seemed worth while to attempt to treat such cases by pharmacologic [prostigmine] rather than by endocrine means.

They showed that twenty-five women who had missed a menstrual period for from three to thirty-five days promptly menstruated after prostigmine therapy, provided, however, that they were not pregnant. They also showed by experiments on pregnant rats and on twenty-three women who had been found to be definitely in early pregnancy that this product did not interrupt gestation.

This work is a noteworthy contribution to research, but as a corollary to their investigation Soskin, Wachtel and Hechter advocate the use of prostigmine as a "therapeutic test for pregnancy." They maintain that if a woman fails to menstruate after the treatment "pregnancy may be diagnosed with the same degree of accuracy as is possible with the Friedman test." In other words, if prostigmine fails to induce menstruation in a woman who is overdue in her menses, she undoubtedly is pregnant.

The authors realized the shortcomings of such a test and qualified their statements by the following assertion:

It must be emphasized that this procedure applies only to delayed menstruation in women who have had a normal menstrual history up to the last period. It does not apply either to early or to prolonged amenorrhea due to endocrine dysfunction or to local organic changes.

It is easy enough to state that if the patient has skipped a menstrual period because of an endocrine disturbance or pelvic abnormality the test is not applicable, but is it so simple to rule out endocrine dysfunctions and pelvic abnormalities? These qualifications are the factors which make the test practically worthless. Any physician can make a diagnosis of early pregnancy and be correct in most instances if he can be sure to exclude all endocrine dysfunctions, all local organic abnormalities, nervous oppression and anxiety, if the patient is found to be in fine health and has always menstruated regularly and on time, when she misses her last menstrual period. It is the most likely diagnosis and can be made from the history alone. It is only when the physician has any doubt from the history and physical examination of the patient that he needs the use of a pregnancy test, and the pregnancy test must have few or no exceptions. That is why the Aschheim-Zondek and Friedman tests have withstood the test of time and why the prostigmine test, with its host of interfering endocrine dysfunctions, pelvic abnormalities and the like, cannot ever hope to be as accurate as the Friedman test.

It is not my purpose in these remarks to refute the work of these investigators but merely to define more clearly the disadvantages and possible sources of error in their suggested test. A test for pregnancy which is not from 98 to 99 per cent accurate need not be contemplated when such accuracy is already

in the armamentarium of the physician. Having recently made a survey of most of the so-called pregnancy tests (*Am. J. Obst. & Gynec.* 35:354 [Feb.] 1938) and having discredited many of the tests which were at first highly praised (i. e. the female bitterling test, THE JOURNAL, April 13, 1935, p. 1318; the intra-dermal test, *M. Rec.* 145:203 [March 3] 1937; the urinary histidine test, *Am. J. Obst. & Gynec.* 35:354 [Feb.] 1938), and so on, I feel that the profession should be cautioned against any test which claims the accuracy of the Friedman test backed by so little basic or confirmatory evidence.

The following seven points are an evaluation of the prostigmine test for pregnancy:

1. The test is valueless (admitted by the authors) when the amenorrhea is due to endocrine dysfunction. But how can the examiner be certain that the case is not an endocrine dysfunction? Occasionally the diagnosis of an endocrine disturbance may be made from the history and physical examination, but this is not always possible. Therefore, to be certain that the amenorrhea is not of endocrine origin, the physician attempting the use of the prostigmine test must first test the patient with all the means at his disposal. To eliminate thyroid dysfunction, a basal metabolism test should be performed. To rule out pituitary disturbances an x-ray film of the sella turcica should be taken, a sugar tolerance test made and possibly the specific dynamic action studied. To exclude the pancreas, the urine sugar and blood sugar must be examined. To dismiss the ovaries, the physician may have to subject the patient to vaginal epithelial studies, quantitative hormone assays, biopsies of the uterine endometrium and the like. And if at the same time the patient shows some hirsutism one must rule out amenorrhea due to an adrenal adenoma, possibly by subjecting the patient to a perirenal gas insufflation with x-ray studies. It all seems so unnecessary when the Friedman test is so simple.

2. The test is worthless (admitted by the authors) when the amenorrhea is due to local organic changes. One may be able to diagnose pelvic tumors by means of a bimanual examination, but it is quite difficult to diagnose an atrophic uterine endometrium, a small corpus luteum cyst, endometriosis, oophoritis and the like without having to resort to special technics to ascertain whether or not the patient is a fit subject for the prostigmine test. Again, the examiner may have to resort to repeated endometrial biopsies, hormone determinations and even a pneumoperitoneum and hystrogram to exclude organic pathologic changes before using the prostigmine test. At times, exploratory laparotomy discloses pelvic abnormality when other means of diagnosis have failed.

3. The test can be of little value in the amenorrhea of the early menopause, since it also is an endocrine change. The menopause must therefore be ruled out by studying the cellular desquamations of the vagina and testing the pH of the vagina at different intervals.

4. There is no physiologic reason why prostigmine should induce menstruation in a patient afflicted with a constitutional disease. The test is therefore valueless in these conditions, and x-ray examinations, blood studies and other procedures must be undertaken to rule out systemic disease in its beginning phase before the new pregnancy test is resorted to.

5. The amenorrhea from beginning anemias and blood dyscrasias offer another stumbling block to the test. Complete blood counts must be resorted to, since moderate anemia will cause the missing of a menstrual period.

6. Amenorrhea following acute infections is usually easy to differentiate from a pregnancy, but gestation may continue along simultaneously with a grip or influenza.

7. It is chiefly in cases of transient amenorrhea from nervous causes in which prostigmine has its physiologic function by inducing the delayed period to appear. In cases of shock, fright, grief, sorrow, anxiety, financial troubles, family troubles, sea voyages, changes in climate and overstudy, delay in menstruation is a frequent occurrence in some women. Prostigmine is probably a valuable adjuvant to treatment in this type of amenorrhea but ordinarily the simple expedient of rest, sedation and removal of the cause is excellent therapy in allowing the menses to reappear.

All that the physician can really tell the patient whose menses were induced by prostigmine is that she was probably suffering from some type of nervous amenorrhea. It is impossible to tell a patient that she is pregnant, using the prostigmine technic, unless the many endocrine dysfunctions, the various possible pelvic abnormalities, the menopause, anemias and beginning constitutional disorders have been definitely and wholly excluded. The simple Friedman test, employing the use of the isolated female rabbit, is 99 per cent accurate, inexpensive and rapid and with few exceptions is rarely wrong in the diagnosis of placental implantation.

A. I. WEISMAN, M.D., New York.

Department of Obstetrics and Gynecology, Metropolitan Hospital.

DIVERTICULOSIS AND DIVERTICULITIS OF THE COLON

To the Editor:—In an article entitled "Solitary Cecal Diverticulitis" (THE JOURNAL, July 20, p. 194) Dr. August Jonas Jr. reported five cases of acute diverticulitis of the cecum, in two of which the age of the patients was under 40. He also collected nineteen cases from the literature, and in seven of these, or 36.8 per cent, the age was under 40.

Dr. Jonas stated that this was "in sharp contradistinction to the age incidence of multiple diverticulitis" . . . that in a Mayo Clinic report "only 5.2 per cent occurred under 40 years of age—a proportion with which other reports are in substantial agreement." While diverticulosis and diverticulitis of the colon are considered to occur usually after the fourth decade, it is not unlikely that diverticulosis, which must precede diverticulitis, is more frequently present in the colon before the age of 40 than has been indicated in the numerous publications on this subject.

The incidence of diverticulosis by decades has been based on postmortem and x-ray examinations. Since, according to a recent report from the Bureau of Vital Statistics, there is but a yearly mortality of 0.45 per cent under the age of 40 years, the figures obtained from postmortem studies cannot be considered as conclusive in establishing the true incidence before the age of 40. Likewise, x-ray studies of the gastrointestinal tract will not show the correct incidence of diverticulosis unless it is considered in the differential diagnosis and special efforts are made to demonstrate the diverticula. Diverticula may be seen following a barium sulfate enema, but at times they are not visible unless a double contrast enema is used. It may be necessary to administer barium by mouth in order to demonstrate them, and in addition these examinations may have to be repeated, since diverticula may not be visible until as late as the fourth or fifth day after the barium sulfate meal.

Diverticulosis of the colon may be present in young persons, and diverticulitis should be considered in the differential diagnosis irrespective of the patient's age.

CARL BEARSE, M.D., Boston.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INDUSTRIAL GOGGLES

To the Editor:—When industrial goggles are worn, is the degree of comfort of the wearer a satisfactory criterion of protection as far as the danger from radiant energy is concerned? Is there any danger to the eyes from visible radiation when ordinary goggles sold by retail stores are used with no technical supervision.

M.D., Illinois.

ANSWER.—The comfort of the wearer is decidedly not an adequate criterion of the protection afforded by special purpose industrial goggles as far as radiant energy hazard is concerned. The effect of ultraviolet, for instance, is often not appreciated at once by the eye any more than by the skin. A few hours or a day later the real effect of the exposure becomes apparent. If, however, it is a question of continued comfort afforded the wearer over an appreciable time, then the comfort of the wearer would be a more adequate criterion except that it is known that certain long red rays of light produce cataract after prolonged exposure without any awareness of optical discomfort.

With respect to the second question, exact definitions are needed. What is meant by "danger to the eyes"? If it is meant that cataracts will be produced, or conjunctivitis or iritis or some other ocular disease, there appears to be practically no danger. Otherwise certainly the literature would be full of remarks on this subject, because millions of pairs of such glasses are being worn and have been worn in the United States for many years. The low priced goggles usually differ from the higher priced goggles particularly in one respect. They are full of optical flaws and consequently their effect on the eye is somewhat the same as the effect of looking through a rain swept windshield of an automobile not equipped with a good wiper. The rays of light are bent to produce irregular astigmatic effects and cause a distortion of images. This produces a feeling of "strain" and a considerable tiring of the eyes. It is conceivable, as certain authorities have proposed, that such strain may interfere with the proper nutrition of the lens. There is no certain knowledge that even this is productive of definite disease.

Some of the low priced goggles have wide opaque side shields. These interfere considerably with the normal protective mechanism of indirect sight, that is, side vision, and such goggles should not be worn either by automobile drivers or by pedestrians who are exposed to hazards such as crossing the streets, for obvious reasons. Probably the best of the low priced goggles on the market for most people are the polaroid.

VACCINE THERAPY FOR DERMATOPHYTOSIS

To the Editor:—What is the status of vaccine therapy for dermatophytosis? I am interested in this in connection with a patient who has responded to mercuriolate medication but for whom it has not accomplished a lasting cure.

Virgil F. Neumann, M.D., Norwich, Conn.

ANSWER.—Opinions regarding the efficacy of vaccines in treating eczematoid ringworm are conflicting. A few find their use of great help, while most observers feel that vaccines for this infection are a failure. Lewis and Hopper in their Introduction to Medical Mycology (Chicago, Year Book Publishers, Inc., 1939) sum up the situation:

"In recent years the use of biologic products (trichophytin) in the treatment of fungous eruption (particularly dermatophytids) has been the subject of much investigation and subsequent discussion. Early reports (such as those of Van Dyck and others) were extremely optimistic. Sulzberger and Wise expressed their enthusiastic belief that a new and useful method of curing recalcitrant lesions had been brought forward. They reported cases in which cutaneous allergy to species of Trichophyton had been relieved by desensitization. Subsequent investigation has produced sharply divided opinions, ranging from that of Traub and Tolmach, who expressed doubt that trichophytin is of any therapeutic value, to that of Robinson and Grauer, who obtained spectacular results with autogenous vaccines. Sulzberger has lately expressed his belief in the soundness of the conception of the principle of desensitization but has admitted that the clinical response to treatment is poor. Combes and some others have held that the principle of desensitization is wrong, as a reduction in the immune forces may follow reduc-

tion in the sensitivity. From our research it seems that in most of the cases of actual fungous infection an increase in sensitivity is desirable (provided that this is linked up with the acceleration of the immune forces). Thus in the infections due to *T. purpureum* the lack of reactions at the site of the trichophytin test after forty-eight hours is too frequent to be ignored as an explanation for the chronicity of this type of fungous disease. In dermatophytid the condition should respond when the residual focus is eliminated. In the cases in which theoretically trichophytin should be of service it is unnecessary. In general, we do not at the present time advocate its use in treating either a definite fungous disease or an allergic manifestation (dermatophytid). This statement holds true for fungous infections due to any dermatophyte and in any site, including the scalp. Considering our results, we are unable to agree that the extravagant claims for one extensively advertised (South American) brand of trichophytin are justified."

TUBERCULOUS ADENITIS AND EDEMA OF LEG AND VULVA

To the Editor:—A Negro woman aged 44 has since September 1939 had a severe chill every three or four weeks. The chills come on without warning and usually last three or four hours. For the first hour they are mild and gradually become so severe that the patient is left in a state of collapse. Fever of 103-104 F. follows for several hours and then drops to the neighborhood of 100 F., where it may remain for several days. She generally stays in bed for a week after each chill because of generalized aching, pain in the lumbar area and pain and swelling of the left leg. Swelling of the vulva follows each chill and may remain until the next chill. When she gets out of bed she feels well except for weakness. No fever is apparent until the onset of the next bout. She has always been healthy. Three years ago she underwent a pelvic operation and the tubes and a number of small ovarian cysts were removed. She menstruates regularly and there seems to be no connection with the chills. Repeated complete physical examinations have revealed but little. The sclerae and mucous membranes are pale, there is a moderate widening of the palpebral fissures, the blood pressure is 98/70, a few fine rales are heard at the left lung base, there is a healed suprapubic midline incision, and there are marked edema of the vulvae, slight tenderness and swelling of the left leg and knee, three fixed and slightly tender glands in the left axilla about the size of olives (the size has varied from time to time) and moderately enlarged left inguinal glands. A complete blood count on Feb. 2, 1940, showed hemoglobin 60 per cent (this was originally 40 per cent and was improved by the injection of a liver vitamin solution), white cells 4,500, red cells 3,230,000 (originally 2,130,000), polymorphonuclears 42 per cent, small lymphocytes 47 per cent and large lymphocytes 11 per cent. No abnormal cells were seen on repeated examination. Urinalysis was negative except for 1 plus albumin on the first examination. The agglutination test was repeatedly negative. Malarial smears were negative. Sick cell smears were negative. A flat plate of the abdomen and a chest plate were negative. A tuberculin test with the first dilution gave a strongly positive reaction, the reacting bulla being approximately 6.5 cm. in diameter (performed recently). A biopsy of the axillary glands revealed tuberculous adenitis in the tissue section. Apparently the process is of tuberculous origin. The mechanism of the chills is vague to me and I cannot find anything in the literature that is helpful. Could the edema be allergic in nature? I should like your suggestions concerning treatment. What of roentgen treatment?

M.D., Florida.

ANSWER.—This presents a difficult problem because the diagnosis of tuberculous adenitis seems insufficient to explain the disabling symptoms. The persistent edema of the vulva and the edema of the left leg following the acute attacks are not likely to be allergic in nature. While one hesitates to make a diagnosis of two pathologic processes in the same patient, there are certain features in this case that makes a double diagnosis tempting. There must be obstruction to the return flow from the lower extremity. This obstruction may be in the venous channels. A pelvic thrombophlebitis would produce such an obstruction, and the repeated chills and fever would be quite in keeping with such a pathologic condition. The question sets out no good reason for a pelvic thrombophlebitis. Has careful inquiry been made into the postoperative convalescence? Was there any suspicion of postoperative phlebitis? The possibility of tuberculous adenitis producing this picture is rather remote. One of the pyogenic organisms is usually the cause.

An obstruction in the lymph channels is a possibility. Tuberculosis might produce this kind of obstruction but again the chills and fever are difficult to explain. Filariasis might produce lymphatic obstruction and would explain the chills and fever, but filariasis is extremely rare in this country. Has the patient ever lived in a part of the world where infestation with *Filaria* is likely?

From the description one would select a pelvic thrombophlebitis as the most likely diagnosis. Roentgen treatment might be helpful but fairly good results have been obtained in recurrent thrombophlebitis with the use of sulfanilamide. It might be helpful to know whether the inguinal glands as well as the axillary glands were tuberculous. If the inguinal glands were nontuberculous it would lend more weight to the diagnosis of a pyogenic thrombophlebitis.

CHRONICALLY INFECTED TONSILS AND BLOOD SEDIMENTATION

To the Editor:—Would foci of infection raise the blood sedimentation rate in a middle-aged person with suspicious tonsils with no other apparent cause for raising the rate? Would that rise in sedimentation rate point to trouble in the tonsils?

H. J. McNally, M.D., Waterloo, Ont.

ANSWER.—By accepting the term "chronically infected tonsils" instead of "suspicious tonsils," and establishing the criteria on which this diagnosis can be made, the query may be answered with some degree of confidence.

Reimann and Havens have suggested that the diagnosis of chronically infected tonsils be made when there are present (a) "persistent redness of the tonsils and adjacent membranes and exacerbations of acute inflammation, often with pain or discomfort on swallowing, with or without regional lymph node swelling and tenderness, (b) systemic signs and symptoms such as fever, leukocytosis and rapid red blood cell sedimentation, or (c) swelling, pain or tenderness of the lymph nodes which receive tonsillar lymph. In other words, there ought to be some clinical or other evidence of actual inflammation of the tonsils before they are regarded as infected."

This excludes the reddened tonsil, small or large, seen in most adults, otherwise healthy, and wherein the change in color is due to the vicissitudes of the years, the use of tobacco, the climatic conditions, fumes, dust, and the like.

In the acute exacerbation of the chronically infected tonsil, the sedimentation rate is often increased. The other signs of infection, however, are as accurate an aid in establishing the presence of local disease.

A rise in sedimentation rate alone and in the absence of such criteria as Reimann and Havens have established should not be used to condemn the ordinary tonsils of adult life.

Stiles and Chapman have recently made cultures from the tonsils and determined by a test of their own devising the relative pathogenicity of the organisms obtained. They have found a relationship between the virulence of the bacteria and the sedimentation rate in the same patient. It will be necessary for this test to become general and for the work to be confirmed before there can be widespread use of this method to judge the presence of disease in tonsils.

DEXTROSE IN DIABETIC ACIDOSIS AND COMA

To the Editor:—There appears to be little unanimity of opinion regarding the use of dextrose in the treatment of diabetic acidosis and coma. Some authorities contend that dextrose in buffering a full amount of insulin develops a hotter fire to combat acidosis and both reduces the hyperglycemia and elevates the carbon dioxide tension of the blood. Other authorities contend that it is more than foolish to add dextrose to a patient already oversaturated with sugar.

M.D., Illinois.

ANSWER.—As the questioner indicates, the problem turns on the need for dextrose in the first few hours of treatment. Some do not favor its use during the early hours of treatment when the blood sugar is high because: 1. No proof exists that injected dextrose is better utilized than dextrose already flooding the body, provided sufficient insulin is supplied; in diabetic acidosis insulin, not dextrose, is lacking. 2. In the severer stages of diabetic coma the injection of dextrose may lead to renal block (Root, H. F., and Riseman, J. E. F.: *The Exceptional Requirement of Insulin and Salt Solution in Diabetic Coma*, *THE JOURNAL*, May 21, 1938, p. 1730). Large injections of dextrose result in oliguria, according to F. M. Allen (*Diabetic Experiments*, *Tr. A. Am. Phys.* 53:320, 1938) even in the treatment of hypoglycemia induced by insulin. 3. When dextrose is administered, the blood sugar ceases to be a reliable guide for treatment. 4. In certain large clinics in which dextrose is not used as a routine, the mortality rates compare favorably with those obtained elsewhere. 5. In teaching students and physicians it is safer to stress the use of large and adequate amounts of insulin than to divert attention to another feature relatively unimportant.

All will agree that during the later hours of recovery from coma, when the falling blood sugar indicates that sufficient insulin has been given to insure utilization of carbohydrate and cessation of ketone production, 100 Gm. or more of carbohydrate should be administered just as to any diabetic patient during days of routine treatment or the treatment of complications.

The primary difficulty in diabetic acidosis is the disturbance in carbohydrate metabolism due to insufficient insulin. Secondary effects are hyperglycemia, glycosuria, dehydration, acidosis, nitrogen loss, hemoconcentration and shock. The primary therapeutic problem is need for insulin.

Dextrose does not cure coma but insulin does.

ROOM TEMPERATURE AND HUMIDITY IN
TUBERCULOSIS

To the Editor:—A young man who developed tuberculosis of the lungs was exposed to same unfavorable conditions when he was employed. An engineer who examined the room reported that it was ventilated by force draft of warm air through a duct 20 by 12 inches. Air movement appeared slight and the room seemed uncomfortably warm and somewhat stuffy. The temperature was 79 F. and the humidity 32 per cent. According to the Guide, published by the American Society of Heating and Ventilating Engineers, chapter 3, modern standards for ventilation at work rooms require approximately 250 cubic feet of air space per person and a floor space of 25 square feet. These figures are conditional on control of temperature, humidity and air movement and for "still air conditions." At ordinary temperatures they represent minimal values for comfort. To what extent—I am exact—would the temperature 10 degrees above normal, workers being in close proximity with another and in contact with tuberculosis, with the floor contaminated by the use of spittoons, increase the danger from droplet infection and increased exposure to respiratory diseases?

M.D., Connecticut.

ANSWER.—A temperature of 79 F. with a humidity of 32 per cent would have no appreciable effect on the danger from droplet infection. In many houses and apartments where people reside the temperature is maintained higher than 79 F. during the winter months, and in the summer much higher temperature is not unusual. The most important factor in the development of tuberculosis in the lungs of the young man mentioned is the tubercle bacillus. It would be important to know whether he had been infected with this organism, as manifested by the tuberculin test, before he was employed and if so whether he actually had clinical disease at the time he was employed. An x-ray examination of the chest would have determined whether there were areas of disease large enough to cast shadows and, if so, laboratory and clinical examinations would have determined whether they were due to tuberculosis.

It is not clear from the question as to whether the person working in close proximity to the patient had contagious tuberculosis and whether the material in and about the spittoons contained tubercle bacilli. If the fellow worker actually had contagious tuberculosis it is possible that he transmitted tubercle bacilli to the patient, and if the patient had never previously been infected his first infection may have developed in this manner. However, the only good evidence would be obtained by applying the tuberculin test through the change from no reaction to a definite reaction while he was in contact with the other employee. Without such evidence it would be impossible to determine whether there is any direct relationship between the disease which the patient now has and the possible exposure to the other employee; that is, there is no evidence to show that the primary tuberculosis complex was not already laid down when the patient began work and that his present disease was not due to endogenous reinfection from the lesions of the old primary complex.

After infection occurs, at any time in life, endogenous reinfections may be responsible for all forms of tuberculous lesions with no further reinfection from exogenous sources. On the other hand, there is some evidence to show that exogenous reinfections can be responsible for new lesions in the body entirely independent of those produced by endogenous reinfections. Therefore it is possible that the patient was reinfected either by the respiratory or by the digestive route if he was working in close contact with a tuberculous employee. However, there is nothing described with reference to the temperature and humidity where he worked that would have any influence on first infection or reinfection with tubercle bacilli through any port of entry.

PREMENSTRUAL MASTOPATHIA

To the Editor:—Will you please give me the recognized therapy for premenstrual mastopatia.

L. C. Howe, M.D., Muscotine, Iowa.

ANSWER.—Premenstrual mastopatia may be considered a physiologic rather than a pathologic lesion and is brought about by some disturbance in one or more endocrine glands. The most disturbing symptom is pain, which occurs characteristically from ten to fourteen days before the menses and involves both breasts and neighboring structures. It is frequently accompanied by other symptoms such as headache, palpitation of the heart, abdominal distention and nervousness. The pain usually ceases promptly with the onset of bleeding. Premenstrual mastopatia or mastalgia frequently occurs in women who have menstrual disturbances or pelvic inflammatory disease.

Unfortunately there is no uniformly successful treatment. A proper brassiere for supporting the breasts is often helpful. At the present time glandular therapy is being used in an attempt to relieve painful breasts. Estrogens have helped some women. Likewise, progesterone administered intramuscularly in 1 or 2 rabbit unit doses every day or every second day of the second

half of the menstrual cycle has been claimed to have helped others. Recently good results have been reported with testosterone propionate. This substance is known to produce varying degrees of involution of the breasts. To obtain relief from breast pains, 25 mg. of testosterone propionate may be given six times during the last fourteen days of the menstrual cycle. This therapy is experimental.

Since nearly every type of endocrine therapy for premenstrual mastalgia is of only temporary benefit, the administration of these endocrine products will have to be continued every month. Occasionally there is a spontaneous absence of pain for one or more months. If, however, there is no response to endocrine therapy or the expense and inconvenience of the treatment are too great and the patient is near the menopause, a premature menopause may be induced by operation or radiation therapy provided the pain is really distressing. Precautions must always be observed in the use of active hormones.

NEPHRITIS OR NEPHROSIS IN SYPHILITIC PATIENT

To the Editor:—A woman, white, 17 and unmarried, came to me for treatment of an acute coryza. She complained in addition of what apparently was a "canker sore" of the mouth. Since I have been administering antisyphilitic treatment since December 1930 to her fiancé I took a Wassermann test, which was negative. In one week a rash appeared on both arms, the legs and the chest resembling secondary maculopapules. A repeated Wassermann test was returned positive. There was no fever, the urine was normal at the first visit and the blood pressure was 124/70. Some swelling of the ankles was present although not severe and not a subjective complaint. At weekly intervals she has received 0.3 Gm. of nearsphenamine and 0.6 Gm. of the same drug. She now has developed generalized anasarca, the blood pressure is 178/100, the urine is that of acute nephritis and although a dietary regimen and daily doses of magnesium sulfate 2 drachms (8 Gm.) have been instituted, there is no improvement other than a fading of the rash. Will you please give me an opinion as to the cause of the acute nephritis and the treatment advised? Are the heavy metals or continuance of arsenic contraindicated? The blood urea nitrogen is 15 mg. The patient still has no subjective complaints.

M.D., Pennsylvania.

ANSWER.—It appears that the patient in question has developed severe renal involvement after the second dose of nearsphenamine given for secondary syphilis. The relationship of syphilis and antisyphilitic treatment to nephritis or nephrosis has recently been discussed by J. H. Stokes (Modern Clinical Syphilology, ed. 2, Philadelphia, W. B. Saunders Company, 1934, p. 689), by J. E. Moore (The Modern Treatment of Syphilis, Springfield, Ill., C. C. Thomas, 1933, pp. 211-213) and by B. M. Baker Jr. (Bull. Johns Hopkins Hosp. 65:196 [Aug. 1933]).

It is almost certain that the renal lesion in this case was not caused by the nearsphenamine. It may be either an acute syphilitic nephrosis or an acute glomerular nephritis unrelated to syphilis, though inadequate information is provided to differentiate between these two conditions. In the comparatively rare nephrosis of early syphilis there is usually massive albuminuria without cylindruria or with relatively few casts (which may be double refractile/lipoid casts), low plasma protein, inversion of the blood albumin/globulin ratio, edema, usually normal blood pressure rather than hypertension, and normal or only slightly disturbed evidence of renal function. A relatively small number of red cells may be present in the urine but usually much fewer in number than in acute glomerular nephritis.

It is suggested by A. R. Rich (Bull. Johns Hopkins Hosp. 50:357 [June] 1932) that acute hemorrhagic nephritis occurring during the course of secondary syphilis may possibly be explained on the basis that syphilitic lesions of the nasopharyngeal mucosa serve as ports of entry for the bacteria commonly known to cause acute hemorrhagic nephritis.

While a differential diagnosis between acute syphilitic nephrosis and nonsyphilitic acute glomerular nephritis cannot be made on the basis of the information given, nevertheless the treatment procedure is virtually identical. The patient should be placed at complete bed rest in a hospital under the usual medical regimen for the treatment of acute hemorrhagic nephritis, including limitation of fluids, diet and a search for and elimination of possible streptococcal foci of infection. Since the patient has early syphilis, antisyphilitic treatment should be continued for the sake of the renal lesion, if it is due to syphilis, for the prevention of even graver relapse in the nervous system, and for protection of the public health.

The trivalent arsphenamines or mapharsen do not produce renal damage of this nature in previously normal kidneys. Nevertheless they should not be given in maximum dosage to patients with renal involvement of this extent. They may, however, be given safely in small doses and at comparatively frequent intervals. For example, the patient may receive nearsphenamine, beginning with a dose of 0.1 Gm., increasing for the second dose to 0.2 Gm. and for the third and succeeding

doses to 0.3 Gm. each, injections being given every second to third day. Mapharsen may be given in an initial dose of 10 mg., increasing to 20 mg. and for the third and succeeding doses to 30 mg., the injections being given daily. The shorter intervals between doses of mapharsen are permissible because the drug is rapidly excreted as compared with neosarsphenamine.

This therapeutic regimen should provide a prompt differential diagnosis between acute syphilitic nephritis and acute glomerular nephritis due to bacterial infection. If the renal lesion is syphilitic there should be prompt and spectacular improvement within a period of two to three weeks.

The administration of preparations of the heavy metals, either bismuth or mercury, should be avoided until the correct diagnosis is clear. If the lesion is syphilitic nephrosis these drugs should not be employed until all evidences of renal damage have disappeared, i. e. from two to three months hence. If, on the other hand, the lesion is acute hemorrhagic nephritis, the time at which heavy metals may be given depends largely on the patient's progress and the possibility that the acute lesion may be transformed into a subacute or chronic form of nephritis.

ABDOMINAL DISCOMFORT IN CHILD

To the Editor:—A boy aged 10 years has been bothered with his stomach for several years. The family at first noticed that he had from one to four stools daily. He complained of general abdominal discomfort, tenderness about the navel and appendix region (appendix removed) and along the left side. Stools appear normal, except for being soft. No mucus or blood was noticed. Hemoglobin has been as low as 65 per cent; the red and white counts are normal; the urine is normal; the chest is normal; there is abdominal tenderness in the cecum, the sigmoid and about the navel. X-ray examination of the stomach shows a hyperactive intestinal tract. In fact, four hours from administration, barium sulfate was all over the rectal region of the bowel. The child is of a nervous make-up. Stools have been checked and are found negative for amebic dysentery. Will you please advise me as to what other pathologic disturbance will cause hyperactive action of the bowel?

Kenneth A. Ohme, M.D., Mitchell, Neb.

ANSWER:—The symptoms of this child as revealed from the history, consisting of a nervous make-up, abdominal discomfort and normal stools, are probably on a neurogenic basis. Organic malformation of the bowel, as Meckel's diverticulum, may cause similar symptoms, though presumably at the time the appendectomy was performed the surgeon explored the intestinal tract for such an anomalous condition. Intestinal parasites, such as roundworm infestation, may cause similar symptoms. Likewise tuberculous ulcers of the intestinal tract may cause such symptoms and it would be wise to rule out tuberculosis by suitable tests. Dietary indiscretions or intolerance to certain constituents of the diet, such as fats or carbohydrates, may produce such symptoms. Finally, allergy to specific food substances may occasionally cause such symptoms.

DERMATITIS FROM HOP PLANT AND DESENSITIZATION

To the Editor:—I am interested in the treatment of contact dermatitis due to the hop plant. Because of the numerous persons in this vicinity affected during the hop season, I would appreciate some suggestions as to a treatment outline or references.

M.D., California.

ANSWER:—The dermatitis caused by the hop plant is probably due to the lipoids or resins found in the plant leaf. These substances are soluble in lipid solvents, as ether, and are the cause of the cutaneous lesions produced by plants.

The best treatment for the dermatitis is the use of protectives for exposed areas, as gum mastic, ethyl cellulose or gloves. If such means of protection are not possible or prove inadequate, hyposensitization may be attempted. Contact dermatitis due to plants is the only type for which there is some hope of relief through hyposensitization. Even here the results of present methods of treatment of the well known and relatively common clinical entities are in dispute. Varying results have been reported in the attempt at hyposensitization for poison ivy and pollen dermatitis. The method commonly used for the preparation of the antigen is ether extraction of the material. The material may then be dissolved to make a 2 per cent solution in an oil, as almond oil, for intramuscular injection. The initial dose usually used is 0.05 cc. of this 2 per cent solution, although it may be advisable, in the absence of knowledge of the potency of the antigen, to start with a lower dose by diluting the original 2 per cent solution with the oil solvent to a 1:10 or even 1:100 strength. The dose may be increased to as high as 1 cc. of the 2 per cent solution by intramuscular injection.

If facilities for the preparation of the material are not available, the plant may be sent to any of the well known pharmaceutical houses for the preparation of the antigen.

ENLARGED SUPRACLAVICULAR LYMPH NODES

To the Editor:—In February 1939 a woman aged about 62 came to me with supraclavicular and cervical glands enlarged on both sides. The right supraclavicular space was filled with these enlarged glands and the left side not quite so much enlarged. She is a widow (third time), has three boys and two girls, men and women grown, and has had no miscarriages (one son and two daughters are married and have children). She has earned a living for herself and the children for the past twenty-five years, until the children were able to take care of themselves. She has worked to care for herself since then. Her general health has been good. In the twenty-five years she has not had to see a doctor more than half dozen times and then not for anything that would put her to bed. Her blood test showed red cells 4,088,000, white cells 5,900, hemoglobin 96 per cent, nonfilaments 25 per cent, filaments 45 per cent, lymphocytes 26 per cent, monocytes 3 per cent and eosinophils 1 per cent. At the time I wanted to take out one of the glands for a biopsy but she felt that she must get back to her work. She returned today saying that the glandular enlargement went down following her visit and remained down till six weeks ago. Now it is showing more enlargement than before and on the left posterior cervical space there is a large gland about 2 by 1 1/4 inches in size like an egg split lengthwise, with smaller ones filling the supraclavicular and cervical spaces. She says that when she was with her son in Manila some five or six years ago she had a similar condition, which left her after a few weeks. She is worried now because this time the glands have persisted longer than at any other time. They are not sore or painful. She is well nourished, large chested, a strong type of woman, about 5 feet 6 or 7 inches tall (170 cm.) and weighs around 170 pounds (77 Kg.). Her Wassermann reaction is negative. Can you give me any indication as to what might cause this trouble in her? I had thought of Hodgkin's disease but when the enlargement disappeared I began to feel that my suspicions were wrong.

M.D., Minnesota.

ANSWER:—It is often extremely difficult to make a differential diagnosis of adenopathy and it seems subversive of the best interest of the patient to attempt to do so without biopsy when this procedure will promptly supply the answer. From the description one can only say that leukemia seems to be ruled out by the blood count, and syphilis seems to be excluded by the negative Wassermann reaction. Hodgkin's disease and lymphosarcoma loom large as possibilities, as do tuberculosis and other less common conditions. Biopsy should be insisted on at once and examination of the tissue by a competent pathologist will be almost certain to furnish the diagnosis. In those rare instances in which the pathologist is puzzled, clinical differentiation is clearly hopeless.

ACNE IN PRIMITIVE RACES

To the Editor:—Can you give me information concerning the incidence of acne vulgaris in Eskimos or among the primitive peoples of Africa, Australia and similar regions? Is there any correlation between the occurrence of acne vulgaris and dental caries?

M.D., Pennsylvania.

ANSWER:—Acne vulgaris among Eskimos, native black Africans, Australian aborigines and Maoris appears to be a much less common disorder than it is among civilized white people. As the Maoris adopt modern methods of living, the condition occurs more frequently. In Ellesmere Island, Somerset Island and Baffin Land one would expect to find a great deal of seborrhea and acne, because the people subsist on a highly fatty diet. They eat practically all their food in the raw state, and no sledge dog could gobble up strips of seal meat faster than a hungry young Eskimo.

Acne as encountered in private practice and in the clinics of the Middle West is practically nonexistent among native Africans. The Kikuyu apparently suffers more frequently than the members of the white tribes who live outdoors and subsist on a simple diet. While dental caries and focal infections of the teeth probably aggravate acne vulgaris, it is doubtful whether disorders of this type ever cause it, *sui generis*.

SCARS OF CORNEA

To the Editor:—Is there anything new, or old for that matter, to remove scar tissue? This is a case of supposedly too strong silver nitrate solution in the eyes of an infant, or it might have been infectious. So far as I know we shall never know. Now there is complete white membrane over the cornea. Theoretically potassium iodide should dissolve scar tissue.

C. B. Kenton, M.D., Artesian, S. D.

ANSWER:—Dense scars of the cornea cannot be dissolved or thinned by any chemical means. Innumerable methods have been reported by many authors with varying degrees of success, but interestingly enough other clinicians were not able to corroborate the results. If the opacity is superficial and thin, peeling of the superficial layers of the cornea is frequently successful in restoring partial transparency. But if the opacity is throughout the thickness of the cornea, total transplantation of corneal tissue offers the only hope. And that can be successful only if the corneal tissue adjacent to the graft is fairly transparent and viable.

SERORESISTANT SYPHILIS IN CHILD

To the Editor:—In the latter part of 1934 I discovered active syphilis in a young girl employed as a maid in the household of a close friend. As one of the children in this house had been ill for some months previously, I investigated the entire family and found that this particular child had a positive Wassermann reaction. Both parents and a younger brother were and have had negative reactions on repeated examinations. The child with the positive reaction of the blood was only 7 years of age at the time and I immediately instituted a rigorous course of intravenous arsenicals alternating with preparations of bismuth. These treatments have now been in force for six years, with little let-up. The spinal fluid gives a negative reaction; the child shows no external evidence of this condition, yet Wassermann reactions of the blood are persistent by four plus. What are the possibilities, after this extensive treatment and after this length of time, of securing a negative Wassermann reaction? What should one do in this case? Should there be a let-up in treatment or should one continue treating as in an early case? What is the outlook for this child as far as a so-called cure is concerned? M.D., New York.

ANSWER:—The situation described by the inquirer of seroresistance in a syphilitic child with apparently latent syphilis who has been treated presumably continuously for six years does not differ in the least from the management of seroresistance in the adult. This situation is discussed in detail in an article by Moore and Padgett (*The Problem of Seroresistant Syphilis: So-Called Wassermann Fastness*, *THE JOURNAL*, Jan. 3, 1938, p. 96).

PULPLESS TEETH AND MOUTH CANCER

To the Editor:—Is there any relationship between "dead" teeth in the mouth, root canal fillings and cancer of the mouth?

M.D., North Carolina.

ANSWER:—The term "dead" tooth as commonly used refers to a tooth the pulp of which has undergone degenerative changes and is no longer vital. Root canal fillings are placed in the pulp cavity, replacing the space occupied by the dental pulp. A tooth in which the roots are filled must therefore be a pulpless or, as often loosely termed, a "dead" tooth. While there may be residual infection in the degenerative pulp tissue of a pulpless tooth or in the periapical region of a pulpless tooth with or without root canal filling, there is no well substantiated evidence to suggest any relation to cancer of the mouth.

RETINITIS PIGMENTOSA

To the Editor:—Please discuss treatment in pigmentary degeneration of the retina, with particular reference to liver and vitamin A therapy, if any.

M.D., California.

ANSWER:—There have been extensive reports in the literature on this subject and as yet there is no unanimity of opinion. Consequently the necessarily abbreviated discussion that could appear in this column would be of no particular value. The reader is referred to the comprehensive article by Joseph Levine that appeared in the *Archives of Ophthalmology* (9:453 [March] 1933) and to the second edition of *Ocular Therapeutics* by S. R. Gifford (Philadelphia, Lea & Febiger, 1937, p. 324). It must be noted in passing that no one clinician nor any one clinic has the opportunity to observe a sufficiently large number of cases of retinitis pigmentosa to be able to judge adequately of the comparative value of the innumerable procedures recommended. Particular attention is called to the use of theelin (estrone) as described in the Gifford textbook. There seem to be more reports of good results from this product than from any other therapeutic procedure ever used.

RIB RESECTION IN EMPYEMA

To the Editor:—Why are acute empyemas always drained by resecting the eighth rib instead of a lower rib? Resection of the lower rib would result in more dependent drainage.

M.D., Alabama.

ANSWER:—Acute empyemas are not always drained by resecting the eighth rib. By whatever method one drains the empyema, one aims at entering at its lowest part. Sometimes this is the eighth rib, sometimes the ninth, sometimes the tenth. It is obvious that the empyema must be drained where it is in contact with the chest wall. Sometimes this is in the anterior part of the thorax. In these cases it may be necessary to resect a segment of the third rib in front. An apical empyema may have to be drained by resection of the second rib high in the axilla or of the third or fourth rib between the spine and the scapula. One never operates for empyema until pus has been aspirated and obtained. One always drains the empyema at a site where pus has been obtained. When an empyema is situated in the usual location in the lower and posterior portion of the pleural cavity, one usually aspirates just over the ninth or tenth

rib. It is usually well to start low and, if one does not get pus at that site, to go over the rib just higher.

It is important to emphasize the fact that there is no standard approach to empyema, because empyema may occur any place in the pleural cavity. Physical and x-ray examinations should localize it and should determine the site of aspiration, which in turn should determine the site of operation.

CULTURE MEDIUMS FOR BACTERIOLOGIC LABORATORY

To the Editor:—I wish to set up a bacteriologic laboratory for the performance of the less specialized cultural methods. I would appreciate your recommendation and outline of the preparation of suitable mediums for such procedures. I do not expect to be able to do the finer methods of isolation and identification but would like to be able to grow out with reasonable accuracy and certainly various exudate and blood stream pathogens.

E. C. Chomberlain, M.D., Fort Lauderdale, Fla.

ANSWER:—Unless it is desired to do extensive work in the identification of bacteria (in which case at least one person might be constantly employed in the preparation and standardization of culture mediums) the most practical procedure would be to obtain a selection of dehydrated mediums. This is added to the proper amount of water, tubed and sterilized as needed.

The Difco Laboratories, 920 Henry Street, Detroit, carry a large assortment of such mediums. On request they send their "Difco Manual," which describes each formula and its use in the growth and isolation of bacteria.

ACID SALIVA

To the Editor:—Can you suggest a method of treatment that will alkalize an acid saliva? The saliva in this particular instance is gradually destroying the teeth. Regardless of the amount of alkali the patient takes, the saliva remains acid. Complete physical examination and routine laboratory examination are negative.

M.D., California.

ANSWER:—The saliva normally is slightly acid but is never sufficiently acid to destroy the teeth when secreted. Any acid condition which would destroy the teeth is probably due to a local rapid fermentation of free sugar. A high protein diet tends to increase the acid neutralizing power of the saliva. A sugar free, high protein diet usually benefits cases of this sort as far as the teeth are concerned. If other conditions which may contraindicate this type of diet, such as inability to utilize starch or protein, are present, dental restoration is the only alternative.

INJECTION OF VAS AND VASECTOMY

To the Editor:—Is there any recognized method of sclerosing the vas deferens, for sterilization purposes, by injection of some sclerosing agent into its lumen? Is any such method in use in dealing with the feeble-minded or insane?

M.D., Illinois.

ANSWER:—No references have been found to any substance being injected into the vas deferens for purposes of sterilization. This procedure would be making a hard job out of an easy one. Sterilization, by removing a section of the vas deferens and overlapping the cut ends and ligating them, is so simple and so sure that there is no necessity for looking for other methods.

"PHYSICIAN, HEAL THYSELF!"

To the Editor:—Will you kindly tell me, if you can, the correct wording and the derivation of the expression "Physician, heal thyself"? I have heard it on numerous occasions but do not know whether or not I have heard it correctly nor do I know whence it came.

M.D., California.

ANSWER:—The phrase "Physician, heal thyself" appears in the Gospel of St. Luke, chapter 4, verse 23, which says "And he said unto them, Ye will surely say unto me this proverb, Physician, heal thyself: whatsoever we have heard done in Capernaum, do also here in thy country."

Incidentally, verse 24, which follows, says "And he said, Verily I say unto you, No prophet is accepted in his own country."

MERCURY BICHLORIDE INTRAVENOUSLY FOR SYPHILIS

To the Editor:—Please tell me if the following method is useful in the treatment of syphilis: mercury bichloride 1:1,000 intravenously, starting in doses of 1 cc. and gradually increasing the dose of 8 cc., giving injections two or three times a week. Please advise me as to the therapeutic value of this method if you have any information.

M.D., China.

ANSWER:—While this therapy was all right in a past generation, it is hardly considered up to date. It would be rather difficult to outline the treatment that should be used, in default of knowledge concerning the symptoms or stage of the disease.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, August 10, page 480.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 17-19. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, Sept. 3. Sec., Dr. W. W. Council, Box 561, Juneau.

ARKANSAS: Regular. Little Rock, Nov. 7-8. Sec., Dr. D. L. Owens, Harrison. *Eclectic*. Little Rock, Nov. 7. Sec., Dr. Clarence H. Young, 415 Main St., Little Rock.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), San Francisco, Oct. 2. *Written examination*. Sacramento, Oct. 21-24. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: Denver, Oct. 1-4. Applications must be on file not later than Sept. 17. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Written*. Hartford, Nov. 12-13. *Endorsement*. Hartford, Nov. 26. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic*. Derby, Nov. 12-13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: Washington, Nov. 11-12. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Tampa, Nov. 18-19. Sec., Dr. W. M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 8-9. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 8-11. Sec., Dr. James A. Morgan, 48 Young Building, Honolulu.

IDaho: Boise, Oct. 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 1-3. Superintendent of Registration, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 17-19. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, Citizens Trust Building, Fort Wayne.

KANSAS: Topeka, Dec. 10-11. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

KENTUCKY: Louisville, Dec. 3-5. Sec., State Board of Health, Dr. A. T. McCormack, 620 Third St., Louisville.

MAINE: Portland, Nov. 12-13. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Medical. Baltimore, Dec. 10-13. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, Dec. 10-11. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 12-14. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Lansing, Oct. 9-11. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, Oct. 15-17. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, Sept. 30. *Written*. Helena, Oct. 1-2. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEW JERSEY: Trenton, Oct. 15-16. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 7-8. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 23-26. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Building, Albany.

NORTH CAROLINA: *Reciprocity*. Durham, Dec. 3. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 7-10. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Oklahoma City, Dec. 11. Sec., Dr. James D. Oshorn Jr., Frederick.

PUERTO RICO: San Juan, Sept. 3. Sec., Dr. O. Costa Mandry, Box 3834, Santurce.

RHODE ISLAND: Providence, Oct. 3-4. Sec., Division of Examination, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 21-22. Dir., Medical Licensure, Dr. J. F. D. Cook, Pierre.

VERMONT: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 4-6. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WEST VIRGINIA: Morgantown, Oct. 31-Nov. 2. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: Madison, Jan. 14-17. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, October. Sec., Dr. M. C. Keith, Capitol Building, Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Tucson, Sept. 17. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.

COLORADO: Denver, Sept. 16-17. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: New Haven, Oct. 12. Chairman, State Board of Healing Arts, Dr. Charles M. Bakewell, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, Oct. 21-22. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Gainesville, Nov. 1. Applications must be on file not later than Sept. 16. Sec., Dr. John F. Conn, John B. Stetson University, De Land.

Iowa: Des Moines, Oct. 8. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Building, Des Moines.

MINNESOTA: Minneapolis, Oct. 1-2. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

NEBRASKA: Lincoln, Oct. 1-2. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

OREGON: Portland, Oct. 26. Sec., Mr. Charles D. Bryne, State Board of Higher Education, University of Oregon, Eugene.

SOUTH DAKOTA: Examination. Yankton, Dec. 6-7. *Endorsement*. Dec. 21. Sec., Dr. Gregg M. Evans, Yankton.

WISCONSIN: Madison, Sept. 21. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

Alaska March Report

Dr. W. W. Council, secretary, Alaska Board of Medical Examiners, reports the written examination for medical licensure held at Juneau, March 5, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Minnesota Medical School.....	(1935)		89
Columbia University College of Physicians and Surgeons (1934)			90

Missouri Reciprocity Report

Dr. Harry F. Parker, secretary, State Board of Health of Missouri, reports twelve physicians licensed by reciprocity and two physicians licensed by endorsement on April 18. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....	(1939)		Arkansas
Indiana University School of Medicine.....	(1923)		Indiana
University of Kansas School of Medicine.....	(1936), (1937)		Kansas
Johns Hopkins University School of Medicine.....	(1936)		Maryland
Boston University School of Medicine.....	(1915)		Kansas
University of Minnesota Medical School.....	(1937)		Minnesota
University of Nebraska College of Medicine.....	(1938)		Nebraska
Cornell University Medical College.....	(1939)		New York
University and Bellevue Hospital Medical College.....	(1929)		Iowa
University of Rochester School of Medicine and Dentistry.....	(1932)		New York
Ohio State University College of Medicine.....	(1935)		Ohio

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad.	of
Washington University School of Medicine.....	(1936)	N. B. M. Ex.	
Cornell University Medical College.....	(1936)	N. B. M. Ex.	

Illinois April Report

Mr. Lucien A. File, superintendent of registration, Department of Registration and Education, reports the written examination for medical licensure (graduates of foreign schools given also a practical test) held in Chicago, April 2-4, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Fifty-eight candidates were examined, fifty-three of whom passed and five failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Chicago Medical School.....	(1940)		80
Loyola University School of Medicine.....	(1939) 80,	(1940)	86*
Northwestern University Medical School.....	(1939) 85,* 87, (1940) 81, 82,* 85		83,*
Rush Medical College.....	(1937) 79, 82,* 83,* (1939) 81,* 82, 84, 86		79,
The School of Medicine of the Division of the Biological Sciences.....	(1939)		79
University of Illinois College of Medicine.....	(1939) 83,*	83, 84*	
University of Oregon Medical School.....	(1937)		84*
Marquette University School of Medicine.....	(1939)		82
University of Wisconsin Medical School.....	(1938)		82*
Deutsche Universität Medizinische Fakultät, Prag.....	(1903)		78
Medizinische Fakultät der Universität Wien (1899) 81,	(1917)		79,
(1920) 81, (1924) 77, 83, (1925) 79, 79, (1926) 76,	(1928) 81, (1929) 81, (1930) 79, 80, (1931) 77,		
(1937) 75, (1938) 80			
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin.....	(1918) 75, (1919) 77,	(1937)	80
Ludwig-Maximilians-Universität Medizinische Fakultät, München.....	(1908)		77
Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau.....	(1924)		77
Universität Köln Medizinische Fakultät.....	(1925) 80,	(1933)	79
Magyar Királyi Erzsébet Tudományegyetem Orvostudományi, Pecs.....	(1929)		75
Regia Università degli Studi di Bologna. Facoltà di Medicina e Chirurgia.....	(1934)		76
Regia Università di Torino Facoltà di Medicina e Chirurgia.....	(1936)		79
American University of Beirut School of Medicine.....	(1926)		82
Universität Bern Medizinische Fakultät.....	(1938)		81
Second Leningrad Medical Institute.....	(1924)		76

School	FAILED	Year Grad.	Number Failed
Chicago Medical School.....	(1937)		1
Leopold-Franzens-Universität Medizinische Fakultät, Innsbruck.....	(1921)		1

Medizinische Fakultät der Universität Wien... (1924), (1936)	2
Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg (1902)	1

Twenty-six physicians were successful in the practical examination for reciprocity and endorsement applicants held in Chicago, April 2-4. The following schools were represented:

School	PASSED	Year Grad.	Reciprocity with
Northwestern Univ. Med. School... (1926)* Minnesota, (1938)			Iowa
University of Illinois College of Medicine..... (1938)			Wisconsin
Indiana University School of Medicine..... (1933),* (1938)			Indiana
State University of Iowa College of Medicine..... (1936, 2)*			Iowa
Johns Hopkins University School of Medicine..... (1936)			Maryland
University of Maryland School of Medicine and College of Physicians and Surgeons..... (1937)*			Maryland
University of Michigan Medical School..... (1934),* (1937)			Michigan
University of Minnesota Medical School..... (1928)			Minnesota
National University of Arts and Sciences Medical Department..... (1916)			Missouri
Washington University School of Medicine (1924),* (1935), (1936),* (1936, 2) Missouri			
University of Nebraska College of Medicine..... (1938)			Nebraska
Temple University School of Medicine..... (1935)*			Penna.
University of Pittsburgh School of Medicine..... (1936)			Penna.
University of Texas School of Medicine..... (1923)*			Texas
University of Wisconsin Medical School..... (1937)*			Wisconsin
School	PASSED	Year Endorsement Grad. of	
Vale University School of Medicine..... (1937) N. B. M. Ex.			
University School of Medicine... (1938) N. B. M. Ex.			
Medical School..... (1938)* N. B. M. Ex.			

* License has not been issued.

New Mexico Endorsement Report

Dr. Le Grand Ward, secretary, New Mexico Board of Medical Examiners, reports thirteen physicians licensed to practice medicine by endorsement on April 9, 1940. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad. of
College of Medical Evangelists..... (1939) N. B. M. Ex.		
University of Colorado School of Medicine..... (1935)		California
Chicago Medical School..... (1935)		Illinois
Keokuk Medical College, College of Physicians and Surgeons..... (1908)		Iowa
Tulane University of Louisiana School of Medicine..... (1938)		Louisiana
University of Michigan Homeopathic Medical School..... (1915)		Michigan
Creighton University School of Medicine..... (1936)		Nebraska
University of Nebraska College of Medicine..... (1935)		Wyoming
Columbia Univ. College of Physicians and Surgeons..... (1932)		New York
Long Island College of Medicine..... (1928)		Nebraska
University of Buffalo School of Medicine..... (1937)		New York
University of Tennessee College of Medicine..... (1935)		Tennessee
Université de Genève Faculté de Médecine..... (1935)		New York

Washington January Report

Mr. N. N. Vaughan, secretary, Department of Licenses, reports the written examination for medical licensure held at Seattle, Jan. 15-17, 1940. The examination covered seven subjects and included seventy questions. An average of 60 per cent was required to pass. Thirteen candidates were examined, all of whom passed. Ten physicians were licensed by reciprocity and three physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists..... (1939)	74		74
University of California Medical School..... (1939)			85
Rush Medical College..... (1939)			84*

Book Notices

The Newer Nutrition in Pediatric Practice. By I. Newton Kugelma. B.S., M.A., M.D., Attending Pediatrician, Broad Street Hospital at Heckscher Institute, New York. Cloth. Price, \$10. Pp. 133, v. 183 Illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1940.

A number of books have been written in recent years on the newer knowledge of the experimental modern science of nutrition. This is the most extensive volume devoted exclusively to this subject as applied to practical everyday pediatrics.

The first section (183 pages) is devoted to nutritional physiology and, as stated by the author, "reveals the physical and chemical basis of the growing organism in terms of the materials of life derived from food, air and water." An understanding of these processes is necessary in the scientific application of nutrition in health and disease. Substantiated scientific procedures are substituted for traditional methods. Among the many subjects discussed are energy metabolism (metabolism standards, energy requirements), protein, carbohydrate and fat metabolism, vitamin metabolism in detail (forty pages) and mineral metabolism, digestion and absorption. This section is interesting and instructive.

The second section (216 pages) deals with nutrition in health and presents established procedure for the advancement of positive health. The author states that "few children attain the degree of physical perfection and resistance to disease which innate capacities permit because of suboptimal environmental conditions . . . the goal is no longer mere freedom from disease but new levels of well-being." Such separate topics are discussed as newborn, premature, infant and child nutrition, infant formulas (types of milks and sugars), body build, feeding behavior and anthropometric measurements. In this section normal infant and child feeding and nutrition are brought down to date.

The third section (700 pages) concerns itself with nutrition in disease. Systemic disturbances primarily affected by nutritional factors have been discussed in great detail, while regional disturbances secondarily related to diet are given more cursory consideration. The author states "we prefer to formulate the principles involved in applying specific foods in diseases as is now universally practiced with other therapeutic agents." Frequently in the text this is exemplified by calculated diets for all age groups. This section is further subdivided into units on digestive, deficiency, metabolic, allergic, infectious and regional diseases.

There is an extensive bibliography following each of the various subdivisions of the book, and the index is well detailed for ready reference. Most of the illustrations are helpful. The reviewer does not agree with some of the illustrations regarding methods of administering parenteral fluids. In most pediatric hospitals subcutaneous injections of fluids are not given in the breast region in children, intraperitoneal injection of fluid has been discarded, and the longitudinal sinus is seldom used any more for blood or any other transfusions, even in an emergency.

The book is well written and easy to read but is unnecessarily long (especially the third section) largely because of two factors: repetition and detailed diet lists. Regarding repetition, for example, diet and nutrition as elaborated in the text should not require a separate division or even a separate paragraph for otitis media, the common cold, acute rhinitis, acute pharyngitis, acute tonsillitis, acute laryngitis or measles. Generally speaking, diets could be grouped and condensed under the general heading of afebrile infectious diseases and febrile ones. There is no specificity of diet for any one of these conditions nor does diet have much influence on the outcome. During an acute illness a child will take little except liquid and soft sweet carbohydrates. As he convalesces his appetite increases and, if gastrointestinal disturbance does not persist, may have his former regular diet as soon as he shows the desire for it. Why go into so much more detail? Other instances of this type could be mentioned. Regarding superfluous detailed diet lists, there are fifty-four pages of detailed ketogenic diets at different pediatric age levels. In man,

large pediatric hospitals and clinics, this type of diet at present is seldom if ever used. Other examples of too much unnecessary detail are specific individually detailed liquid and soft diets for children 2, 4, 6, 8, 10, 12 and 15 years of age, as well as complete separate diets for children of these various age groups with tuberculosis. The general principles of the type of diet for tuberculous children should be sufficient, as there certainly is no specific diet for childhood tuberculosis, as one would be led to believe from this textbook. The same type of specifically detailed diets are given for typhoid, nephrosis, nephritis, diabetes and other conditions at various ages.

The pediatrician certainly does not need these specific detailed diet lists, and the general practitioner usually has in his library volumes dealing with general dietetics containing diet lists, which could by common sense be applied to children as well if necessary.

This volume represents an overemphasis on diet in the treatment of many pediatric conditions. It emphasizes specific amounts of food and caloric requirements, whereas the sick child or even the well child will eat only what he cares to eat, calories or no calories. It might mislead the uninformed by this overemphasis to force diets on sick children to their detriment, for fear of otherwise dire results.

This would be a better and more practical volume if to the excellent first two sections on nutritional physiology and nutrition in health were added a much more condensed section on nutrition in disease, pointing out that the general idea of feeding a child with childhood tuberculosis is to give him a well rounded, high caloric diet and really admitting that, even if he eats whatever he likes within reason, he will probably recover nicely. Specific foods in pediatric diseases other than dietary deficiency diseases can be overstressed.

The Kosher Code of the Orthodox Jew: Being a Literal Translation of That Portion of the Sixteenth-Century Codification of the Babylonian Talmud Which Describes Such Deficiencies as Render Animals Unfit for Food (Hilket Terefet, Shulhan 'Arukh); to Which is Appended a Discussion of Talmudic Anatomy in the Light of the Science of Its Day and of the Present Time. By S. I. Levin, Senior Rabbi of Minneapolis, and Edward A. Boyden, Professor of Anatomy, University of Minnesota, Minneapolis. Cloth. Price, \$4.50. Pp. 243, with 5 illustrations. Minneapolis: University of Minnesota Press, 1940.

This book constitutes the first attempt to study the Jewish law regarding fit and unfit animal food from an anatomic point of view. In order to do that, the authors made a literal translation of the sixteenth century codification of the Babylonian Talmud relating to diseases which make animals unfit for eating. After this had been done, one of the authors reviewed the anatomic portions of the law and evaluated them in the light of modern anatomic knowledge. These two diversified portions of the study brought together the strange combination of authorship, namely that of a Rabbi and of a professor of anatomy. The book, with the hundreds of notations, is intended for scholars. The average medical reader, however, will find in it enlightenment on the anatomic knowledge of the Jewish sages during the postgalenic period of medicine. Boyden believes that, as a whole, talmudic medicine is nearer that of the hippocratic than of the galenic school. As to the talmudic contribution to anatomy, Boyden states that probably the greatest single contribution of the Talmudists was the gross anatomy of the surface of the lungs, worked out in some detail by the Amoraim of the third and fourth centuries. According to him, these men and their successors were the first to record the number of lobes, to establish their fundamental asymmetry and to anticipate the modern conception of lobes as outgrowths of a stem bronchus. In addition they described the mediastinal pocket of the infracardiac lobe and the visceral pleura as well as visceral and parietal layers of the pericardium. Also they noted that adhesions arise from spittle-like exudates which congeal into membranes at the site of perforations of the lung, and distinguished them from normal membranes. Regarding the digestive system, Boyden asserts that the Talmud correctly describes the parts and action of the ruminant stomach and has provided the present day term "omasum." The rectum and anal columns were likewise named, but otherwise no distinction was made between the large and the small bowel. Probably this section contains the earliest accounts of duplication of the intestines and of the cloacal vents of birds. Of special interest is the first

description of the cauda equina by the physician Samuel (third century) and the later verification of the fact that paralysis of the legs follows severance of the spinal cord (Rabina, fifth century). The Talmud also supplies one of the earliest descriptions of young human embryos—in this case viewed under olive oil in the sunlight (Abba Saul and others, second century). In addition there are numerous first accounts of agenesis and duplication of various organs, together with such anomalies as atresia of the esophagus and of the bronchial tubes, hypospadias, and Meckel's diverticulum ilei.

The Content of Cells and Proteins in the Normal Cerebro-Spinal Fluid: The Diagnostic Importance of Demonstrating Small Pathological Changes in the Cells and Proteins; The Technique of the Investigation. By Axel V. Neel, M.D., Pathologist at the Psychiatric Laboratory, University of Copenhagen, Copenhagen. Paper. Price, \$2.75. Pp. 141. New York & London: Oxford University Press; Copenhagen: Ejnar Munksgaard, 1939.

The author has in this small monograph given a comprehensive and detailed discussion on the subject of the content of cells and proteins in normal and pathologic spinal fluids. He states, "The examination of the cerebrospinal fluid is the most important clinical laboratory examination in neurology and psychiatry. Gradually such an examination has, indeed, come to play a considerable role in the diagnosis of doubtful diseases in internal medicine and pediatry." Between the blood and the cerebrospinal fluid there is a barrier which does not allow protein or other substances of a colloidal nature to pass, while substances of a different nature (electrolytes, dextrose, uric acid, creatinine, nonprotein nitrogen) found in the blood are able to pass into the cerebrospinal fluid, where they can be demonstrated in a quotient which, for some substances (sodium chloride and magnesium) is greater than that in which they occur in the blood. The examination of the spinal fluid for sugar and for protein is important, but from the point of view of a differential diagnosis the importance is lessened. It has also been mentioned that with a decrease of the permeable substances in the blood a corresponding decrease is found in the cerebrospinal fluid. The author's purpose for this splendid monograph is to understand the normal cerebrospinal fluid as regards its content of cells and protein. He has reviewed the English and foreign literature and has offered interpretations with regard to the technique of the various tests and the differences in the normal figures that are found in the French, German and English literature. This monograph is recommended to all physicians, particularly the neurologists and psychiatrists.

Sexual Pathology: A Study of Derangements of the Sexual Instinct. By Magnus Hirschfeld, M.D. Authorized translation by Jerome Gibbs. Originally published in 3 volumes. Cloth. Price, \$2.95. Pp. 368. New York: Emerson Books, Inc., 1940.

Magnus Hirschfeld, prior to the Nazi régime in Germany, was the unquestioned leader in the diagnosis and treatment of psychologic sexual disorders. He founded the first and the greatest clinic for handling cases of fetishism, impotence, sexual crimes and domestic maladjustment. Dr. Hirschfeld allegedly examined hundreds of thousands of cases and had histories which included some of the most important personages in Germany. His writings, which were considered sound by the majority of experts in his own field, were extensive. The present volume is strangely reminiscent of Krafft-Ebing's "Psychopathia Sexualis." It deals essentially with the same subjects: perversions, strange sex conduct and interests, hypersexed individuals and cases of impotence. There is not much discussion about the cases, nor is the work tabulated in systematic form. The actual chapter structures are much like those of the earlier writers on this subject, but the chapter divisions are more modern, as they are based on the mechanism accompanying the strange behavior rather than the type of overt abnormal sex act. Hirschfeld's case histories are not as extensive or perhaps even as interesting as those of Krafft-Ebing, but the value of the book lies not in the story of the deviant but rather in Hirschfeld's experienced and detailed explanation of the mechanisms involved in the medicolegal significance of the case as it was brought out in court, when there was a court hearing, and in his numerous references to means of treating the situation. It is a less interesting book for those who are looking for sexual *curiosa* because of the fact that the approach is moderately technical, for there is a proper use of medical terminology and the style lacks

drama. Although it is not all inclusive, most of the perversions and psychosexual problems that occur in the experience of the average physician are covered here. In view of the fact that our problems in the United States do not seem to be as extensive along these lines as they are in Europe and Asia, the average physician would not have as great need for this book as perhaps does the average European psychologist, psychiatrist or private practitioner. However, any physician who has a practice presenting a number of psychosexual problems should find this book of some value. Because it was written some years ago and has just now been translated and published in this country, it is somewhat outdated.

Treatment by Manipulation. By A. G. Timbrell Fisher, M.C., M.B., Ch.B., Orthopedic Surgeon to the St. John Clinic and Institute of Physical Medicine, London. Being the third edition of "Manipulative Surgery." Cloth. Price, \$3.75. Pp. 255, with 68 illustrations. New York: Paul B. Hoeber, Inc., 1939.

A valuable book on manipulative treatment, dealing with the application of carefully controlled movements of a forced and specialized nature to joints the movements of which are restricted, with resulting painful interference with function. The history of bone setting is traced into the past through the activities of such men as John Hunter, John Hilton, H. O. Thomas, Sir James Paget and Wharton Wood. The cult of osteopathy is discussed and the conclusions of the Select Committee of the House of Lords relating to a bill for registration and regulation of osteopaths are presented. This is a crushing indictment of the cult in its claims. The development of restricted joint function is discussed from a pathologic point of view, also the prevention, diagnosis and treatment of adhesions in general, in three chapters. The indications, technic and after-treatment of lesions of the lower and upper extremity as well as those of the spine and sacro-iliac joint are dealt with at length. The book concludes with a chapter on the contraindications of manipulation. This interesting treatise on manipulation should prove to be of great interest to the orthopedic surgeon and to all others engaged in treating dysfunction of joints of traumatic or other origin.

The Rise of Embryology. By Arthur William Meyer. Cloth. Price, \$6. Pp. 367, with 97 illustrations. Stanford University, California: Stanford University Press; London: Oxford University Press, 1939.

The chief aim of the author has been to give the history of the basic ideas in embryology. He begins with the ideas on reproduction held by primitive people, who associated fertility and conception with the sun, the moon and the stars. Even at present, among some Hindus, a childless woman stands naked, after bathing, facing the sun and invokes his aid to remove her barrenness. The remote ancestors of civilized people probably held opinions about reproduction similar to those current among primitive peoples of today. The story lacks chronological continuity, because some of the records are missing. The author does not pretend to write a history but selects and restricts his material. As would be expected, the chapter on spontaneous generation ends with reference to Pasteur's experiments, which about 1861 completely explained phenomena that had baffled investigators for centuries. In the chapter on the search for the mammalian ovum the quotation from Galen suggests that Herophilus, about 280 B. C., was the first to describe the mammalian ovary. Credit is given to von Baer for discovering the mammalian ovum, but much is said about William Cruikshank, who was a neglected but deserving seeker for the ovum. Cruikshank's experiments were read before the Royal Society by Sir Everard Home, brother-in-law of John Hunter, in 1797. His observations were so accurate and his experiments so well planned that one marvels how he missed discovering the ovum, or why it was thirty years after his paper was published and forty-nine years after his experiments were performed that von Baer accidentally recognized it. Other seekers of the ovum were Prevost and Dumas, who correctly surmised that the graafian follicles had once contained the "little ovules of the horns." Chapters follow on the discovery, origin and meaning of the spermatozoa, impregnation, the problem of malformation, the growth of morphology, and on early experimental embryology. There are sixty pages of reproduced illustrations, a bibliography in the back of the book, and an index.

Compendium of Regional Diagnosis in Lesions of the Brain and Spinal Cord: A Concise Introduction to the Principles of Localization of Diseases and Injuries of the Nervous System. By Robert Bing, Professor of Neurology, University of Basel, Switzerland. Translated and edited by Webb Haymaker, Assistant Clinical Professor of Neurology and Lecturer in Neuro-Anatomy, University of California, San Francisco. Eleventh edition. Cloth. Price, \$5. Pp. 292, with 132 illustrations. St. Louis: C. V. Mosby Company, 1940.

The translation of this compendium into English will make the monograph popular because of its tremendous teaching value to the medical student. It is clearly and concisely written and its pages are full of practical points on cerebrospinal localization. The compendium has been increased from 200 to 275 pages with many new and more accurate ideas of localization which have been worked out in the past several years. There are two parts to the monograph: localization of spinal cord lesions and localization of cerebral lesions. In the first part there is a discussion of spinal cord lesions both in the transverse and in the longitudinal plane. This is an excellent departure from the usual book, which attempts to teach memorization of symptoms of disease entities instead of teaching certain fundamental signs and symptoms and then interpretation. In the second part are discussed lesions in the brain stem, cerebellum, cerebrum, basal ganglions and hypophysis. Many of the illustrations are colored.

Fisiopatología del hepato-colédoco: Colangiografía operatoria. Por Pablo L. Mirizzi, profesor titular de clínica quirúrgica de la Facultad de medicina de Córdoba. Cloth. Pp. 282, with 190 illustrations. Buenos Aires: Librería y editorial "El Ateneo," 1939.

The author has evidently made extensive use of cholangiography. Those not familiar with this subject will be enlightened to learn that it is now possible to study the biliary system by the injection of opaque oil into fistulas or at operation by injecting the gallbladder or the biliary ducts. Immediate x-ray films are highly instructive. The opening chapters deal with the anatomic and physiologic considerations, illustrated by numerous roentgenograms of the opacified hepatic and common ducts. The rest of the book is devoted to the employment of biliary tract visualization at the time of the operative act. Due credit is given to American, French and German authors who have done much to develop and popularize the method. Numerous illustrations, most of them clear and interesting, illuminate the text. The book is a veritable atlas of interesting cases. Operative cholangiography has been of great use. The accurate interpretation of the shadows is in general easy, but valuable experience with the systematic examination of hundreds of cases aids greatly in protection against errors. Among the causes of error in interpretation may be mentioned defects of surgical technic causing wounds of the biliary passages, the injection of the contrast substances outside the biliary tract, or the accidental ligation of one or more of the bile ducts. The contrast medium may be injected under low pressure and in excessive quantity. Air may be injected and cause error.

Unto the Fourth Generation: Gonorrhea and Syphilis. What the Layman Should Know. By Irving Simons, B.S., M.D. Cloth. Price, \$2.50. Pp. 243, with 18 illustrations by M. Emanuel, M.D. New York: E. P. Dutton & Co., Inc., 1940.

This book fails in its avowed purpose of being written for the layman alone and not for the physician. A large share of the material in it is of interest only to the physician. The presentation of controversial matters in the field of venereal diseases will do little but add to the confusion of the reader and may tend to increase the phobias that he may already possess, or it may well introduce new ones. There is little that the reader will benefit from statements in the book such as "On examining the patient there will be noted a large liver, saber tibia" or that "shot like lymph glands are found in the neck, groin or armpits." True these are symptoms of one of the venereal diseases, but there is no need for this detail on how to diagnose a disease. Many of the illustrations are excellent but unfortunately a few are decidedly out of place. One showing a woman with a little child and with the caption "One Child Sterility—A gonorrheal woman can usually give birth but once" is quite likely to be misunderstood. Not all cases of one-child sterility are due to gonorrhea and yet that is the impression that this illustration makes. Some of the statements the author makes are not clear and can easily confuse the reader. The final chapter, labeled "scientific addenda,"

contributes little toward the education of the nonmedical reader. To understand this chapter demands a sound understanding of bacteriology. The author speaks of reagin, amboceptor and antigen, which are not words in the common vocabulary of the layman. The book cannot be recommended for the lay reader.

Lehrbuch der röntgenologischen Differentialdiagnostik der Erkrankungen der Brustorgane. Von Dr. med. habil. Werner Teschendorf, Chefarzt des Strahleninstituts der allgemeinen Orskrankenkasse Köln. Paper. Price, 69 marks. Pp. 803, with 891 illustrations. Leipzig: Georg Thieme, 1939.

This magnificent publication represents about the best of publications on roentgenology of the lungs. It is most comprehensive and abreast of the time. The text includes differential diagnosis of diseases of the lungs, diseases of the heart and the maladies of the esophagus and the diaphragm. One searches in vain for any serious oversight. The text is full and rather easy to read. Due attention is paid to roentgen kymography, which is explained at considerable length. Especial consideration is given to accurate identification of the actual sites of bronchial strictures in bronchogenic carcinoma. Laminagraphy comes in for extensive discussion. There are a number of illustrative roentgenograms which draw a convincing parallel between the laminagram and the ordinary roentgenogram in the diagnosis of certain lesions. In the discussion on the heart, kymography and electrocardiography are both associated with the ordinary roentgenogram in a highly instructive manner.

Skin Hazards in American Industry. Part III. By Louis Schwartz, Medical Director, U. S. Public Health Service. From the Division of Industrial Hygiene, National Institute of Health. Prepared by the direction of the Surgeon General. Federal Security Agency, U. S. Public Health Service. Public Health Bulletin No. 249. Paper. Price, 15 cents. Pp. 93, with 22 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

Schwartz has extended his observations of skin irritants into an additional list of industries—citrus fruit; cigar; acid; pulp and paper; organic solvents; chromic acid and chromates; iron and steel; paints, varnishes and lacquers; glass; photographing, photo-engraving, lithographing, printing, typewriting, and hectographing; and explosives. The industrial operations and materials are fully described in the text. Extensive lists of potential irritants have been prepared under certain of these headings, which in the case of glass amount to nearly a hundred different substances. Multiply examples of this kind by the total number of industrial operations, and the complexity of the problem as a factor in occupational diseases can be comprehended. There are, however, methods of protection which are discussed. Each subject has its own bibliography but the individual irritants are not separately indexed. This pamphlet again demonstrates the enormous superiority of color plates as a means of demonstrating characteristic cutaneous changes.

The Pathology of Internal Diseases. By William Boyd, M.D., LL.D., M.R.C.P., Professor of Pathology and Bacteriology in the University of Toronto, Toronto. Third edition. Cloth. Price, \$10. Pp. 874, with 357 illustrations. Philadelphia: Lea & Febiger, 1940.

This readable book has proved especially valuable to students for correlating their early courses in pathology with clinical medicine. The organization of the third edition is the same as that of previous editions, and the contents cover the pathology of most common diseases other than the more purely surgical conditions. Though much new material has been added, the book has been condensed rather than expanded. This has been accomplished by deletions as well as revisions and by relegating to small type material of subsidiary importance. The most extensively revised sections are those on the pathology of the heart and coronary arteries; diseases of the lungs, particularly lobar pneumonia, silicosis and bronchogenic carcinoma; and diseases of the kidney, revised with reference to the newer work in pathologic physiology. There are also considerable changes in the sections on some of the endocrine disorders, anemias and diseases of the spleen and lymph nodes. The classified bibliography has been supplemented and revised. A number of new illustrations have been substituted for the previous ones, and the addition of eighteen engravings and four color plates makes this an unusually well illustrated textbook.

Steckschuss und Röntgenstrahlen: Untersuchung und Behandlung der Steckschüsse. Von Prof. Dr. Rudolf Grashey. Boards. Price, 8.70 marks. Pp. 92, with 116 illustrations. Leipzig: Georg Thieme, 1940.

This book condenses into less than a hundred pages the description of nearly every useful method of foreign body localization which has been developed. The illustrations look familiar; many are duplicates of those used in the war of 1914-1918. Almost no difference can be discerned between the methods described in this work and those employed twenty-five years ago; neither do we find any new methods. Considerable attention is given to the Dessane Bonnett and similar devices for employing the x-rays fluoroscopically in the full light of the operating room. Description is also given of the method of utilizing the usual fluoroscopic equipment for aiding the surgeon in the extraction of projectiles. This is a timely publication from the point of view of the Germans and should serve to stimulate interest in this same subject in the United States.

L'anoxémie: Ses effets—son traitement. L'oxygénothérapie. Par Léon Binet, professeur de physiologie à la Faculté de Paris, Madeleine Bochet, assistante, et M. V. Strumza, assistant à la Faculté de médecine de Paris. Paper. Price, 60 cents. Pp. 95, with 26 illustrations. Paris: Masson & Cie, 1939.

Binet presents an excellent statement of the consequences of anoxemia as it affects the heart, the brain and the blood. Chapter three of part one contains an interesting presentation on the effect of drugs on resistance to anoxemia. The second half of the volume is concerned with the effect on the lungs and other organs of prolonged exposure to almost pure oxygen. It is well illustrated by photomicrographs of the pathologic changes in the viscera of guinea pigs thus exposed. Similar effects, though less advanced, were observed after a longer exposure to 70 per cent and even to 60 per cent oxygen. Oxygen therapy is well presented, especially the mechanical apparatus for the maintenance of artificial respiration. Several devices not commonly used in America are pictured, such as portable respirators which cover only part of the body. The small "spiropore of Woillez" for the newborn should be of interest to obstetricians and practitioners in rural districts. Apparently the deficiencies of a Bourdon tube gage for therapy have not been recognized on the continent. Unfortunately there is no index and only a poor table of contents.

Savill's System of Clinical Medicine Dealing with the Diagnosis, Prognosis, and Treatment of Disease for Students and Practitioners. Edited by Agnes Savill, M.D., and E. C. Warner, M.D., F.R.C.P. Eleventh edition. Cloth. Price, \$9. Pp. 1141, with 193 illustrations. Baltimore: William Wood & Company, 1939.

As was said when the last edition appeared, any book which goes into the eleventh edition or which has to be republished nine times in twenty years must have much in it that appeals to physicians and satisfies their needs. It is the sort of textbook of medicine which the medical student likes because it is brief and the headings are prominent and easy to follow. Probably the main value of the book is for the student who wants help in gaining his first introduction to internal medicine.

Displacement of the Calcified Pineal Body in Roentgen Pictures as an Aid in Diagnosing Intracranial Tumours: An Anthropometrical-Statistical Analysis. By Bengt Lilja. Acta Radiologica, Supplementum XXXVII. Paper. Price, 10 Swedish kroner. Pp. 183, with illustrations. Stockholm: P. A. Norstedt & Söner, 1939.

This monograph proposes to determine the limits of normal variation in the position of the pineal body by the use of modern anthropological and statistical methods. By a review of the previous literature the author demonstrates the need of a more accurate method than that proposed by Vastine and Kinney and others. He used as material a series of 200 normal x-ray photographs of adult skulls from the Serafimer Hospital, all of which had been taken by the standardized technic of Lysholm. After discussing the various possibilities of error due to the technic of x-ray photography, to the method of measurement and to individual variation in the size of the skull, the author establishes the values for eleven radii with their standard deviation and mean with standard error; the directly observed measurements of the radii were calculated as percentages of the skull length and skull height for practical use. When this information obtained from normal skulls was used to interpret the measurements of the skulls of 217

patients with brain tumor from the clinic of Olivecrona, the author found a displacement greater than the normal limit of variation in 37 per cent. In the case of supratentorial tumors the pineal shadow was displaced significantly in 50 per cent of the cases, in infratentorial tumors in only 14 per cent. By supratentorial tumors the pineal body was shown to be almost always displaced backward and downward. A brief abstract is given of each of the 217 cases with the measurements of each. Finally a table of figures for different degrees of displacement is given with a statement as to the probability of any case being pathologic. This table is meant to be used in clinical work. One is impressed by the scientific accuracy of this study. It is presented clearly in excellent English and should be indispensable to every roentgenologist.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Use of Operative Surgery by Osteopath Unlawful.—Frankowsky, an osteopath, was licensed in Illinois to treat human ailments without the use of drugs or operative surgery. He was convicted of performing a surgical operation without a license authorizing him so to do in violation of the medical practice act of Illinois. On appeal the constitutionality of the medical practice act was upheld by the Supreme Court of Illinois and on that court's transference of the case to the appellate court of Illinois, first district, the judgment of conviction was affirmed. *People v. Frankowsky*, 368 Ill. 171, 13 N. E. (2d) 178; 296 Ill. App. 637, 15 N. E. (2d) 894; abstr. J. A. M. A. 112:1633 (April 22) 1939. Frankowsky thereupon appealed again to the Supreme Court of Illinois.

The information or indictment charged that on March 4, 1937, Frankowsky had treated a patient's rectal fissures by hypodermic injection of procaine hydrochloride or cocaine, by cutting and clipping tissues of the rectum with a metal surgical instrument and by prescribing the use of a medicine known as "proctologic dionol." In the opinion of the Supreme Court, of the acts charged the evidence clearly showed that Frankowsky on the date in question did cut or clip tissues of the rectum. There can be no doubt, said the court, that this act was a surgical procedure. Even though he did not, on March 4, commit all of the acts charged in the information, he did on that day treat a human ailment by operative surgery which he was not licensed to do and so he was guilty of a violation of the medical practice act.

The court could not agree with Frankowsky's contention that a prima facie case of violation of the medical practice act had not been made out because the state had failed to prove that his license limited him to practice the healing art without operative surgery. In the opinion of the court, it was not necessary that the state offer such proof. In fact, the information did aver in effect that he lacked a proper license to perform a surgical operation. In a penal action for violation of a statute, said the court, when the question of due license to practice a certain profession arises, the burden of proving a proper license rests not on the state but on the defendant.

For the reasons stated, the Supreme Court affirmed the judgment of conviction.—*People v. Frankowsky* (Ill.), 21 N. E. (2d) 582.

Life Insurance: Total and Permanent Disability Construed.—The defendant company issued a life insurance policy to Gibbons whereby it promised to pay him certain benefits and waive payment of further premiums if he should "become totally and permanently disabled and will for lifetime be unable to perform any work or engage in any business for compensation or profit." In April 1933 Gibbons, who had been employed by the American Steel & Wire Company for forty-eight years and at that time was a night roll superintendent, was "seriously stricken with ulcers and suffered a severe hemorrhage." He spent several weeks in a hospital and was confined to bed at

his home for months thereafter. He attempted to work again but was able neither to perform the strenuous physical work required by his prior job nor to perform even the light work required by the job of night watchman. He had hemorrhages from his duodenal ulcer or ulcers as late as September 1937. The defendant company refused to pay benefits for total and permanent disability or to waive the payment of further premiums, whereupon Gibbons instituted action in the form of two separate suits. From judgments in favor of the plaintiff, the company appealed to the Supreme Court of Ohio.

The phrase "totally and permanently disabled" within the meaning of a policy of insurance, said the Supreme Court, should be given a liberal interpretation. To be totally disabled it is not necessary that the insured be so utterly helpless as to be incapable of performing work of any kind for remuneration or profit, but it is sufficient if he is unable to perform any work or engage in any business for compensation or profit for which he was qualified. In the judgment of the court, the insured in the instant case was totally disabled from performing the work for which he was qualified. The court took cognizance of the medical testimony adduced by the defendant to the effect that Gibbons' disability was temporary in that following hemorrhages he was disabled but after such bleeding subsided he was capable of resuming work. In holding that nevertheless Gibbons' disability was permanent, the court said that a disability need not continue until death in order to be permanent. For its decision the court relied on the fact that another provision in the insurance policy in question provided that, notwithstanding proof of total and permanent disability, no benefits would be paid and no premiums would be waived if the insured, on demand by the insurer not oftener than once a year, failed to furnish proof of continuance of his disability or if he was found after a medical examination to be able to perform any work or engage in any business for compensation or profit. This provision, therefore, clearly recognized that for purposes of the policy a disability to be permanent need not necessarily be lifelong. Accordingly, the judgments in favor of the plaintiff were affirmed.—*Gibbons v. Metropolitan Life Ins. Co. (Ohio)*, 21 N. E. (2d) 588.

- Pacific Association of Railway Surgeons, Reno, Nev., Sept. 20-21. Dr. W. T. Cummins, 1400 Fell St., San Francisco, Secretary.
- Pennsylvania, Medical Society of the State of, Philadelphia, Sept. 30. Oct. 3. Dr. Walter F. Donaldson, 500 Penn. Ave., Pittsburgh, Secretary.
- Utah State Medical Association, Ogden, Aug. 29-31. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.
- Washington State Medical Association, Tacoma, Aug. 26-28. Dr. V. W. Spickard, 1305 Fourth Ave., Seattle, Secretary.
- Wisconsin, State Medical Society of, Milwaukee, Sept. 18-20. Mr. J. G. Crownhart, 110 East Main St., Madison, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Variations in Normal Precordial Electrocardiograms: Report of Observations on 100 Normal Subjects. R. L. Shanno, Forty Fort, Pa.—p. 713.
- Studies on Coronary Occlusion: I. Effects on Electrocardiogram of Cat of Producing Anoxemia After Coronary Artery Ligation. W. S. Scott Jr., A. Leslie and M. G. Mulinos, New York.—p. 719.
- Basal Metabolic Rate in Organic Heart Disease. H. J. Stewart and N. B. Jack, New York.—p. 738.

Action of Certain Drugs on Induced Anoxemia.—Levy and his co-workers studied the effect of various drugs on the occurrence of pain and on the form of the electrocardiograms of ten patients with coronary sclerosis. The technic used was that for inducing oxygen want by enabling the patient to breathe a mixture containing a constant percentage of oxygen at a rate comparable to normal pulmonary ventilation. The data of eighty-six tests and 739 electrocardiograms were pooled, averaged and compared with controls. 1. Aminophylline in doses of 0.48 Gm. intravenously prolonged the appearance of pain in 63 per cent and diminished the RST deviation by 58 per cent. The T waves were modified in seven of the ten patients. 2. Glyceryl trinitrate caused a prolongation of 51 per cent in the time of appearance of pain and diminished the RST deviation by 47 per cent. The T waves of six patients were modified. 3. Aminophylline prolonged the appearance of pain in 26 per cent, diminished the RST deviation by 32 per cent and modified the T waves of four patients. 4. Lactose caused only a 2 per cent prolongation in the time of appearance of pain, and the change in RST deviation was 13 per cent. The T waves of four patients were modified. 5. Erythrol tetranitrate prolonged the appearance of pain of 2 per cent, diminished the RST deviation by 26 per cent and modified the T waves of four patients. 6. Digitalis shortened the time of appearance of pain by 9 per cent, diminished the RST deviation by 40 per cent and modified the T waves of seven patients. There were no constant relationships between changes in heart rate, blood pressure, the occurrence of anginal pain and changes in the form of the electrocardiogram. It appears that when aminophylline is taken orally it exerts a beneficial action in certain cases of cardiac pain by causing dilatation of the coronary vessels. The result probably depends on the anatomic condition and physiologic state of the coronary circulation. Criteria for the selection of suitable cases are not yet at hand. Glyceryl trinitrate dilates the coronary arteries of patients with coronary sclerosis and for this reason is effective in relieving anginal pain and not because it lowers systemic blood pressure. Erythrol tetranitrate is not effective in raising materially the threshold for cardiac pain. The increase in the tendency to pain of digitalis does not appear to be due to coronary constriction.

Arteriosclerosis of Coronary Arteries and Their Occlusion.—Horn and Finkelstein studied 100 hearts which at necropsy showed evidence of recent occlusion of the coronary arteries either by thrombosis or by massive hemorrhage into

their walls or both. The main branches of the coronary arterial tree exhibited advanced sclerotic changes with approximately equal frequency, although the incidence in the anterior descending branch of the left coronary artery was perhaps slightly higher than elsewhere. Arteriosclerotic changes were infrequent in the intermuscular branches of the coronary arteries. Vascularization of the intima was found only in the presence of arteriosclerosis. Intramural hemorrhage was frequent and was always associated with vascularization and plaque degeneration. It invariably originated within the wall rather than by imbibition from the lumen. Coronary artery occlusion was produced by intramural hemorrhage in 62.5 per cent and by the formation of a thrombus on an arteriosclerotic plaque in 37.5 per cent. Intramural hemorrhage led to coronary artery occlusion by inducing acute degenerative and reactive responses in the plaque overlying the hemorrhage, by obstructing the artery mechanically or by dissolution and rupture of the intimal layer. The change is dependent on the vascularity of the plaque and the degree of its degeneration. Occlusion of a coronary artery produced by the deposition of a thrombus on a plaque was usually secondary to an edematous, acute, reactive or degenerative change in the subendothelial tissue. The coexistence of recent and organizing changes within a plaque or its thrombus supports the belief that coronary artery occlusion may be a slow, progressive process. The right coronary artery was the most frequent site of acute occlusion. Simultaneous multiple occlusions were common. Fibrinoid-like masses within arteriosclerotic plaques were considered to be the sequelae of intramural hemorrhages or extravasated blood plasma originating from the mural capillaries within the plaque. Calcification was frequent within degenerating plaques. The only correct pathogenic evaluation of old arterial lesions is a statement of the extent and degree of arteriosclerotic change. A prominent adventitial perivascular infiltration with lymphocytes was often encountered in arteriosclerotic vessels. Medial atrophy was frequent and appeared in direct proportion to intimal thickening. Arteriosclerosis was observed in every instance in which a partial or complete arterial occlusion was found. From the morphologic analysis, coronary artery occlusion is an incident in arteriosclerosis.

Acute Coccidioidomycosis with Erythema Nodosum.—According to Smith, an investigation was made of 432 patients with San Joaquin fever, valley fever or desert rheumatism, in Kern and Tulare counties, Calif., during the seventeen months beginning December 1937. All the patients recovered without sequelae. This disease, characterized by influenza-like prodromes followed by erythema nodosum with or without erythema multiforme, was frequently confused with influenza, pneumonia, tuberculosis, measles and smallpox, and occasionally even with poliomyelitis, typhoid and syphilis. The incubation period ranged between one and three weeks. Sensitivity to coccidioidin, a product of the causative fungus, *Coccidioides immitis*, was established in from two to seventeen days after the onset of

symptoms. The erythema nodosum was associated with the hypersensitivity of freshly acquired allergy. This allergy, apparently like tuberculin sensitivity, was of long duration. Consequently, second attacks were rare (two in the series). Coccidioidomycosis with erythema nodosum was rarely if ever a contact infection. Apparently the disease was acquired by inhalation of the chlamydozoospores. The seasonal incidence corresponded to the climate and the agricultural activities, with the peak in the dusty fall and the ebb in the wet winter. The benign valley fever was most common among white females in contrast with coccidioid granuloma, which is known to be especially prevalent among dark-skinned males. Nearly half of the patients had resided in the San Joaquin Valley less than one year, while only one ninth had been in the region ten years or more. Eventually most of the inhabitants of the region undergo an infection with Coccidioides. As erythema nodosum does not develop in more than 5 per cent of those infected, the series represented between 8,000 and 10,000 attacks of coccidioidomycosis.

Bronchopulmonary Mycosis.—According to Vadalà the most important locations affected by mycotic infections are the tissues of the respiratory tract, and mycotic infection of the lungs is more prevalent than is generally suspected. It should always be considered in patients with pulmonary symptoms resembling tuberculosis whose sputums are consistently negative for tubercle bacilli. The diagnosis of primary bronchopulmonary mycosis is often not made until postmortem and microscopic examinations of the tissues reveal the true nature of the infection, the presence of fungi in the sputum during life having been considered as insignificant contaminants. The fungi that invade the bronchopulmonary system are yeastlike organisms (cryptococci, oidia, monilia, saccharomyces and endomyces) and filamentous forms, such as the actinomyces group. The repeated finding of a fungus in sputum from a patient suffering from mild or severe pulmonary inflammation is strong presumptive evidence of a fungous infection. While this of itself is not sufficient to make a diagnosis of primary infection, the absence of any other definite etiologic evidence supports such a diagnosis. A

mycotic infection may run a mild course in which the patient's general condition remains good with little fever and a few chest symptoms resembling a chronic bronchitis. These cases frequently clear up without complications. But there is another more serious type which runs a malignant course. The patient loses weight and has a cough with hemoptysis. The sputum frequently has a nauseating foul odor which is of diagnostic aid. The physical signs and character of the disease resemble those of tuberculosis. Examination of the chest may show rales and patches of dullness. Roentgenograms cannot differentiate between the two diseases because the changes are similar. The diagnosis depends on aspirating affected exudate and developing cultures on specially prepared mediums. The characteristic observation in most of these infections is the disproportion between the symptoms and the amount of pathologic change. The cough is usually only moderately severe, without a large amount of expectoration; there is a possible fever, and the leukocyte count is seldom more than 10,000. A history of a previous influenza or pneumonia is often elicited suggesting the importance of lowered tissue resistance in its production. According to Vadalà, during the last five years 350 cases have been referred to him for diagnostic bronchoscopy, which have comprised cases of bronchitis, silicosis, pulmonary tuberculosis and asthma. At the time of the endoscopic examination, routine cultures were taken from each of the large bronchi and examined for fungi. A survey since 1919 shows that numerous clinical diagnoses of bronchiectasis and pulmonary tuberculosis have been made without the presence of tubercle bacilli in the sputum. In a certain number of these, postmortem examination revealed pulmonary mycosis. Roentgenograms of mycotic or pulmonary tuberculosis suspects with no tubercle bacilli in the sputum are available in all these cases. The clinical histories of eleven cases, illustrating the characteristic changes present in such cases, are reported. The difference in the pathologic picture presented by the various mycoses (actinomycetes, moniliasis, bronchomoniliasis, coccidioidomycosis, sporotrichosis, blastomycosis and aspergillosis) in their invasion of the bronchopulmonary system are made evident by a detailed discussion of the several principal types of this group of infections. Treatment of mycotic infections depends on isolation of the organism. The iodides offer the most hopeful method of cure, making differentiation from tuberculosis imperative, as iodides in tuberculosis are detrimental.

Bronchoscopy for Postoperative Atelectasis.—Perrone states that bronchoscopic treatment of postoperative atelectasis is by no means a strenuous procedure, as the actual operating time is only two or three minutes. He reports the ninety cases encountered in six years at the Mercy Hospital, Pittsburgh. Sixty-five of the patients were male and twenty-five female. Nine patients were between 7 and 15 years of age, fifteen between 15 and 30, forty between 30 and 50, and twenty-six between 50 and 85. Sixty-five cases followed operations on the upper part of the abdomen (cholecystectomy, gastrojejunostomy or appendicitis). Although gas and ether or ether alone were the most common anesthetics, atelectasis followed any type of anesthesia, even spinal and local. Seventy-four of the cases occurred between thirty-six and forty-eight hours following operation. Three cases occurred less than twelve hours after operation. Thirty-five cases occurred in the right lower lobe, twenty-three in the right lower and middle lobes, seventeen massive atelectases in the right and eight in the left lung and seven in the left lower lobe. The earliest manifestation of pulmonary atelectasis is the elevation of temperature, and then dyspnea, cyanosis, rapid pulse and chest pain. The relative mildness of the respiratory symptoms in some cases is explained on the basis of a gradually developing atelectasis and a gradual alteration in the intrapleural pressure and the vital capacity. The early diagnosis is at times dependent more on the physical examination than on x-ray observation. This is especially true in cases with minor degrees of atelectasis and in those in which the involved area lies within the cardiac shadow on the left side. The heart was definitely shifted in fifty-three, questionably in twenty-five and in twelve cases no displacement could be demonstrated. Bronchial obstruction is the most important factor in producing atelectasis. Its removal is most satisfactorily achieved by bronchoscopic aspiration. Once the obstruction is

removed, the lung reinflates. During the operative procedure, secretions that have collected in the pharynx, nasopharynx and trachea should be removed by suction. If an inhalation anesthesia is employed, a light narcosis should be used whenever possible to preserve the cough reflex. Carbon dioxide for inducing hyperventilation for deoxygenating is of aid, but it does not prevent atelectasis. Atelectasis occurred with almost equal frequency among both the long and the short operative procedures. The postoperative position for least impediment of respiratory movements and for a greater vital capacity is the Fowler position with, whenever possible, frequent changing. Treatment should be instituted as soon as the diagnosis of atelectasis is made. A plan which the author found satisfactory is to stop all sedatives, encourage the patient to cough, move him from side to side and give carbon dioxide inhalations. If any improvement is to take place with this procedure it does so within eight to ten hours. If no drop in pulse and temperature or improvement of physical signs occurs a bronchoscopic aspiration is performed to remove the mucous plug. The aspiration is done in bed. In fifty-eight cases, after bronchoscopic aspiration, a drop in temperature, pulse and respiratory rates occurred in twelve hours, in twenty-two in twenty-four hours and in three in thirty-six hours. The patient almost immediately feels relieved of dyspnea and is able to cough up with ease any secretion which has not been aspirated. All the sputums showed pneumococci of some type. The largest number were type IV. All but seven patients made uneventful recoveries following bronchoscopy. One died of peritonitis and at necropsy the lung was found to be normal. The remaining six died of pneumonia.

Implantation of Synthetic Hormone for Addison's Disease.—The synthesis of desoxycorticosterone acetate is the first instance in history in which a hormone has been synthesized before being isolated from its natural source. Firor determined the daily requirements of the hormone in sesame oil for seventeen patients with Addison's disease before implanting pellets of the hormone. He found that 0.5 mg. of the hormone in oil, given by daily injections, corresponds to a tablet weighing 125 mg. As many as twelve pellets were inserted through a single incision. The incisions are carried well into the subcutaneous fat. The pellets placed in the seventeen patients have met their requirements for cortical hormone for periods ranging from four to nine months. Several of the patients have had their second implantation, and in one of these it seems that there has been partial regeneration of cortical tissue. All but two of the group have returned to full activity and are working as strenuously as they did previous to their illness. Every patient has gained weight. The improvement in both diastolic and systolic blood pressure has been uniform. None of the patients have shown any suggestion of hypertension. All the patients had maintained a positive sodium and chloride balance. They have kept normal concentrations of potassium, sodium and chloride ions in the blood plasma. Similarly, the hematocrit and plasma volume determinations returned to normal after

treatment was begun and have remained so. Some of the patients have shown a decrease in the pigmentation of their skin, but none have lost all the pigmentation. No patient has shown any untoward effect from the treatment. The author warns that, since the rate of absorption depends on the consistency and surface area of the pellets, improperly prepared pellets might crumble and cause a too rapid absorption of this potent hormone. Patients suffering from Addison's disease should be under careful supervision for at least two weeks after the implantation of the pellets. At present the government has not authorized the sale of desoxycorticosterone acetate nor has it been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

Frequency and Diagnosis of Hiatal Hernia.—Guthrie and Jones state that the incidence of hiatal hernia is higher than one would expect. Many more cases are being recognized each year than previously. If the condition is kept in mind when examining the patient with atypical gallbladder or stomach complaints, a larger number will be discovered. Low substernal distress, inconstant and mild in character, especially after large meals, is an important symptom. The roentgenologist should always examine the esophagus and the stomach with the patient in the recumbent and upright positions. It is well to know that the condition exists so that in the event of an increase in symptoms the patient will not undergo a needless operation for a suspected abdominal lesion or be placed on a cardiac regimen. Not all of the lesions are surgical conditions and conservatism can be adhered to in many cases. At the Guthrie Clinic there were five cases of hiatal hernia from June 1927 to January 1938 in which operation was performed. Since then and up to November 1939 fourteen cases have been encountered. Ten of the fourteen patients have been females. Nine were treated by conservative means. One was treated conservatively plus a dilation of the esophagus. For another a phrenectomy was the only operative procedure. On three, phrenectomy was performed and the enlarged hiatal opening was repaired.

Hemolytic Jaundice.—Brenizer reports four cases of the congenital (familial) and two of the so-called acquired type of jaundice. The six cases illustrate most of the observations on hemolytic jaundice. The two acquired cases would seem sporadic and individual as far as a thorough inquiry into the two family histories shows. The author believes that the acquired type is much more severe than the congenital or familial type. Hemolytic jaundice is an entity and should be easily recognized by a syndrome consisting of acholuric jaundice, enlarged spleen, anemia, crises with pain and fever, increased fragility of the erythrocytes, increase of reticular cells, urobilin but no bilirubin in the urine, normal colored stools, increased icterus index, negative direct van den Bergh with positive indirect van den Bergh reaction and absence of itching. The congenital or familial type may embrace all cases. Hemolytic syndromes are probably due to hemolysins, possibly of different types and present in different amounts, functioning slowly in some cases and violently in others. The hemolytic anemias are in all probability due to the effects of the varying activity of hemolysins. Splenectomy offers its greatest triumph in treatment. There are few operations as dramatic. A gain of a million erythrocytes may be obtained during its performance. The autotransfusion and deluge of erythrocytes into the blood stream are life saving. Further study of the reticulo-endothelial system, bone marrow and liver might aid in establishing a more definite pathologic groundwork for hemolytic jaundice, especially since the organ removed shows but little histopathologic change. The fact that it shows little change beyond the engorgement with remnants of erythrocytes and their pigment is one of the most characteristic points of hemolytic jaundice. The liver and kidney are often as much pigmented, and the considerably enlarged liver before splenectomy is of normal size four months after operation. Gallstones and evidence of cholecystitis figure high in cases of hemolytic jaundice. Since the removed spleen has little to show for itself pathologically, but its removal usually brings about a cure, what stops the destruction and fragility of the erythrocytes? While congenital and acquired hemolytic jaundice are chronic, one of their characteristics is the attacks or crises of erythrocyte destruction.

Retrolbulbar Neuritis.—Carroll reviews the data in 100 cases of retrolbulbar neuritis observed during four years and examined by him. During the same period he encountered sixty-five patients with "toxic" amblyopia associated with deficient diets or with excessive use of tobacco or alcohol. Also excluded from discussion is toxic amblyopia produced by known toxic agents: lead, arsenic and thallium. Complete neurologic, x-ray, allergic and medical examinations were carried out so that an etiologic diagnosis could be established. The average age of the patients when first examined because of blurred vision was 32.7 years; the extremes were 7 and 70. The causative factors in the 100 cases seemed to be multiple sclerosis in thirty-seven, Leber's disease in nine, encephalomyelitis in eight, arachnoiditis in three, vascular disease in three, sinusitis in two, syphilis in two, postspinal anesthesia in one and neuromyelitis optica in one. The cause of the retrolbulbar neuritis was not determined in thirty-four cases. If the etiologic agent is known, treatment should be directed toward its elimination. When it is unknown, treatment is of questionable value. Hospitalization during the acute attack is probably advisable. Tumor of the brain and tobacco-alcohol amblyopia are to be differentiated from retrolbulbar neuritis. Most patients noticed sudden decrease of vision in one eye. Sometimes this was observed on waking in the morning and sometimes while working or playing. The vision grew worse after the first change. A few patients reported loss of sight in one eye or in both eyes with no further change or with subsequent slight improvement. A few patients stated that vision had decreased in the two eyes gradually and at about the same rate. The two eyes of seventy-eight patients were involved, often not at the same time. Many patients complained of a large blindspot in the center of vision, and some with bilateral spots stated that they saw better in dull light. Pain was an important symptom. Twenty patients volunteered the information that the involved eye was painful on movement; others admitted having pain when questioned. The eyeball was often tender to palpation. Sometimes pain was referred to as "deep" or "behind the eyeball." Other patients had severe headaches at the time of onset. The cause of the headaches is speculative. A mild, localized meningeal involvement may be the cause in some cases. The visual acuity in the involved eyes was markedly reduced in most. The characteristic field change was a central scotoma. There was usually no change in the normal appearance of the disks in the early stages of the disease. Blurring of the margins of the disk occurred sometimes. Pallor of the optic nerve usually developed temporally after a few weeks.

The unreliability of contraction of the pupil to light as a sign of retrolbulbar neuritis was indicated by its demonstration in several normal eyes.

Convalescent Blood for Herpes Zoster Ophthalmicus.—Gundersen adds twelve cases of herpes zoster ophthalmicus to the ten reported in 1935 in which the transfusion of from 250 to 450 cc. of convalescent blood was beneficial. The result of the present cases confirm the previous conclusions. Of the twenty-two patients who were treated, eighteen retained useful vision (better than 6/18) in the affected eye and four lost useful vision. Of thirty-nine similar patients who received no specific therapy, fifteen lost useful vision and five had seriously impaired vision. The author concludes that, if the convalescent serum is given before ocular infection is well established, good results may be expected.

Splenectomy in Banti's Syndrome.—According to Barg and Dulin there have been forty-three cases since 1922 at the State University Hospitals of Iowa which have fulfilled the diagnosis of Banti's syndrome. Half of these patients (twenty-two) were treated by splenectomy and the remainder conservatively. The two groups are compared to determine the effects of splenectomy. The operative deaths numbered six (27 per cent) and two additional patients died in the hospital. Of the fourteen patients who left the hospital, twelve have been followed. Four of these have died: three from gastro-esophageal hemorrhage and one from an unknown cause. Four are alive and have been free from all symptoms for from two to nine years. Two are much improved. The remaining two have occasional esophageal hemorrhages and one of them requires frequent paracentesis. Of the twenty-one patients on whom splenectomy was not performed, six are living. Two have been in fair health, but in some of the others the symptoms showed a progressive increase. Eleven of the twenty-one are known to be dead; one lived for three years, and all the others died within one year after discharge from the hospital. The authors believe that splenectomy is the treatment of choice in Banti's disease and should be performed in the early stages. It may be contraindicated in elderly patients because of the high operative mortality, but three of the patients who were over 60 years of age have been greatly improved after operation. Splenectomy relieved the ascites. An extensive collateral circulation is developed between the region of the splenic bed and the abdominal walls. The authors do not perform an omentopexy, although in some of their recent cases the greater omentum has been rotated into the splenic bed, as it is felt that this increases the collateral circulation. Splenectomy has not assured relief

from gastro-esophageal hemorrhages. Patients with rapidly developing symptoms before operation respond poorly to splenectomy.

Injection Treatment of Hernia in Older Patients.—Manoil presents a brief analysis of cases of hernia treated by the injection method. During the period between February 1936 and February 1939, 158 hernias in 123 patients were treated by the injection method at the author's clinic. Ninety-two per cent of these patients were between 41 and 90 years of age. Recurrence took place in twenty-six, or 16.4 per cent, of this group, and five patients, or 3.2 per cent, were operated on after injection, making a total percentage of failures of 19.6. In the fifteen younger patients between 11 and 40 years of age there were no recurrences. There were no infections and no mortality. The author believes the injection treatment to be indicated in older patients who are considered poor surgical risks and because of their state of nutrition or other coexisting conditions. It is also indicated in younger patients who refuse operation but are willing to cooperate in this treatment even though it is prolonged. Best results may be expected in the case of a small inguinal hernia. This series, however, includes not only large indirect inguinal but direct inguinal, postoperative recurrent inguinal, scrotal, femoral, umbilical and postoperative ventral types. Most of these were of many years' duration. All of them can be helped provided they are completely reducible and can be kept reduced with comfort during the course of treatment. In addition to a safe and effective sclerosing solution, the use of a well fitting truss is essential. It must be worn day and night during the course of injections, which takes from six to eight weeks if given two or three times a week. Thereafter the patient may remove the truss at night but must wear it during the day for from four to six months.

Effect of Exercise on Blood Volume.—Kaltreider and Meneely determined the volume of blood at rest and during and after varying grades of exercise in seven normal subjects and in five individuals with heart disease. The blood hemoglobin and viscosity, serum proteins and venous pressure were studied. In normal individuals during moderate exertion there was a prompt and definite decrease in the plasma volume accompanied by a corresponding decrease in the blood volume, while the changes in the cell volume were variable though slight. These changes were associated with an increase in the blood hemoglobin and viscosity, the serum proteins and the venous and arterial pressures. Following exercise the plasma volume gradually increased and twenty-five minutes after exercise the plasma volume, blood hemoglobin and serum proteins reached the preexercise values. During exhaustive exercise in normal subjects there was a further decrease in plasma volume accompanied by a moderate increase in the cell volume. Twenty-five minutes after exercise the plasma volume was still diminished and the blood hemoglobin and serum proteins were increased. In patients with compensated heart disease the changes in the blood volume during and following exercise were similar to those of normal subjects. The increase in erythrocytes and hemoglobin concentration resulting from exercise is brought about mainly by passage of protein-poor fluid from the vascular system into the interstitial spaces. New cells are added to the circulating blood only during severe or exhaustive exercise.

Serum Urate in Relatives of Gouty Persons.—Talbott presents data obtained from a five year investigation of 136 blood relatives of twenty-seven persons with gout. A clinical diagnosis of gout was apparent in each of the patients, and in twenty-three there was x-ray evidence of gouty arthritis. The concentration of serum urate was determined four or more times. In all but one patient it was greater than 6 mg. per hundred cubic centimeters. In patients with unexplained joint disease with no renal insufficiency or leukemia, an elevation of serum urate above 6 mg. constitutes evidence, except in patients more than 60 years of age, of gouty arthritis. Not one of the 136 relatives appeared to be suffering from gout or gouty arthritis; two had rheumatoid arthritis, six degenerative joint disease and two rheumatic heart disease. The remainder were in apparent good health. The concentration of serum urate was determined one or more times in each relative and the concentration of 102 was less than 6 mg. per hundred cubic centimeters; average, 4.6 mg. The serum urates of the remaining thirty-four relatives

ranged from 6.1 to 10.8 mg. per hundred cubic centimeters; average, 7.3 mg. The determination was repeated in thirteen of these subjects one or more times within four years of the original observation and found elevated. The serum nonprotein nitrogen concentration was less than 35 mg. per hundred cubic centimeters in each instance. Intravenous phenolsulfonphthalein and urine concentration tests were studied in a few and found normal. Other causes of increased serum urate were excluded tentatively by the medical history and by physical examination. It is concluded that an elevation of serum urate is intimately associated with the constitutional gouty diathesis and is not the result of renal disease. Three of the thirty-four subjects have since had one or more attacks of acute arthritis. One or more joints of the legs were involved. X-ray changes or subcutaneous tophi were not demonstrable. A presumptive diagnosis of gout is probably justified in these three subjects on the basis of family history, elevated serum urate and an acute attack of arthritis. Not one of the 102 subjects who had a concentration of serum urate less than 6 mg. per hundred cubic centimeters has had any acute attacks suggesting gouty arthritis.

Sulfanilamide in Subacute Bacterial Endocarditis.—In the past nine years, seventy-six proved cases of subacute bacterial endocarditis, according to Steele, were treated at the University of Chicago Clinics. The diagnosis was based on the presence of active endocarditis, fever, positive blood culture and

embolic phenomena. Eighteen of the cases were treated with sulfanilamide. Cases in which *Streptococcus viridans* was grown on blood culture were considered. These fourteen cases were studied in order to determine the effect of the drug on bacteremia, fever and time of survival. Sulfanilamide therapy had no effect on the general course of thirteen cases of subacute bacterial endocarditis. The main beneficial effect was a fall in the number of bacteria in the blood stream. In one case there was a definite drop in the temperature curve coincident with the administration of sulfanilamide; in other cases it was thought possible that lowering of the level was related to use of the drug. No severe toxic effects were noted. One case of hemolytic anemia was observed. There was one case of dermatitis believed due to sensitization of the skin to sunlight by sulfanilamide. Nausea, headache and papilledema were also noted and were believed to have been caused by the drug. Ten of the forty patients in whom the date of death could be determined had received sulfanilamide. These ten survived from one to eleven months after onset, the average being 5.6 months. In the thirty patients who had received no sulfanilamide, the time of survival ranged from two to seventeen months, the average being 5.6 months. Thus the average survival was the same in the two groups, but three of the patients who received no sulfanilamide survived longer than eleven months, whereas none of those treated with the drug did. This might be interpreted as indicating that sulfanilamide actually shortened the time of survival.

Puerperal Fatality and Loss of Offspring.—Yerushalmy and his associates state that among 255,727 resident mothers of New York State (exclusive of New York City) there were 258,525 live and still births during 1936, 1937 and 1938. During this time 1,122 puerperal deaths were recorded. A thorough search of the vital statistics files produced birth and stillbirth certificates for 689 deliveries in which death of the mother occurred. For the remaining 433 deaths for which no birth certificate could be found, it was established with reasonable certainty that 224 of the maternal deaths were associated with abortion or miscarriage, seventy-four were ectopic pregnancies, ninety-three died undelivered, twenty-four probably died undelivered and in eighteen it was questionable whether death was associated with the delivery of a viable offspring or with an abortion or miscarriage. Some of these may represent unregistered births. The death certificate of infants who died within one month was matched with the birth certificate of the same one infant as were the death certificates of the mothers and the birth certificates of the infants. The information from the matched certificates was brought together on a single punch card. The average interval between the birth of a child and the death of

a mother was 9.1 days. The first twenty-four hours (37 per cent) after delivery was the most hazardous time. Similarly, the first hour after the birth took the greatest toll of children. Mothers dying from hemorrhage survived the shortest average interval (2.2 days), mothers dying from septicemia the longest interval (18.6 days). The death of a mother and the loss of an offspring were associated. The puerperal fatality rate was 19.3 per 10,000 deliveries when the infant was born alive and 298.7 when the infant was born dead. The rate for mothers whose infants survived the neonatal period was 16.6 and for mothers whose infants died in less than one month it was 108. Similarly, the stillbirth rate was 27 per thousand total births for infants of surviving mothers and 300.4 for infants whose mothers died in childbirth. Septicemia was the most frequent cause of death for mothers of live births and toxemia for the mothers of stillbirths. The average interval between delivery and death for mothers whose infants were born alive was 10.9 days, for mothers of stillborn infants 4.9 days. Mortality of both mother and infant increased sharply when pregnancy terminated prematurely. The puerperal fatality rate was 20.1 when birth was at term and 141.3 when it was premature. For premature stillbirth infants it was 247.8 and the neonatal mortality rate was 373.8. Septicemia was the most common cause of death of mothers who went to term and toxemia for the mothers of premature deliveries. No difference was noted in the puerperal fatality rate by sex of the infant, while the stillbirth and neonatal rates were higher for boys than for girls. The respective rates for males and females were 29.4 and 26 for stillbirths and 34.2 and 25.6 for neonatal mortality. The puerperal fatality, stillbirth and neonatal mortality rates of plural births were three times as high as those for single births. The stillbirth rate for illegitimate infants was 60 and the neonatal mortality rate 63.2 as compared to the total respective rates of 27.8 and 30.

Cancer of Ovary.—Meigs presents the results of 154 operations for cancer of the ovary at the Massachusetts General Hospital from 1901 through June 1934. Only twenty-five, or 15.5 per cent, of the patients are living. The tumors were of

all sorts: large, small, papillary, smooth walled, cystic, solid, solid and cystic, white, yellow, hemorrhagic. They were divided into solid (the true solid tumor, the solid tumor with necrotic areas in it and the solid tumor with definite epithelial lined cystic areas in it, papillary and not papillary) and the definite papillary cystadenoma with small or large papillary projections inside and/or outside the tumor. The entirely solid and solid plus cystic carcinoma of the ovary is by far the most serious group. About one fourth are inoperable and the symptoms are of short duration. Some of the tumors have cystic areas in them but they are usually due to necrosis. The study of these tumors has made such an impression that if in the future there is any question of an ovarian tumor in any patient, or if the ovary is hard or unusual, the patient will either be examined with the peritoneoscope or operated on. It is inexcusable to observe and wait. In patients in menopause it is his intention to be radical. In the series discussed 44.4 per cent of the tumors were bilateral and only 9.3 per cent of the patients are living. Therefore both tubes, both ovaries, the uterus and cervix should be removed if possible. Even if there is no evidence of tumor in the other ovary it should be removed. Conservation of an ovary in a patient who has a solid epithelial tumor of one ovary should not be attempted. These tumors metastasize far and wide: to the umbilicus, the axilla, the bone. Malignant papillary cystadenomas are cystic and papillary. They may have large or only small masses of papillary tissue. The wall of the cyst may be penetrated or the papillary areas may be entirely enclosed. They are frequently adherent and may become widespread throughout the peritoneal cavity. The omentum may occasionally be full of tumor. They metastasize far and wide, as do the solid tumors. Because they are papillary, which means slower growth, and fewer become densely adherent or break through the wall of the cyst, the results are better than in the solid tumor. These tumors are frequently bilateral, 32.9 per cent. It is easy to conceive that a malignant tumor may develop in the other ovary and therefore both ovaries should be removed. The prognosis of the malignant papillary cystadenoma is about the same as that of other types of malignant disease. The rupture of cysts before and during operation is condemned, but the results of the series do not support the condemnation. Spilling of cyst contents should be avoided. Roentgen treatment to date has not proved of much curative value but more modern methods may.

Appendicitis Among the Aged.—Stalker points out that from 1 to 2 per cent of all cases of acute appendicitis occur in patients more than 60 years of age. The mortality among them is reported at about 25 per cent. General peritonitis and pneumonia are the most frequent fatality causes. Pulmonary embolism, cerebrovascular accidents, heart failure, septicemia, intestinal obstruction and other conditions account for some mortality. Eighty-two patients between 60 and 78 with appendicitis were seen from 1924 through 1938 at the Mayo Clinic. The appendix was ruptured in fifty-one and appendectomy was performed in twenty-six of these and in each of the thirty-one cases without rupture. In the remaining twenty-five ruptured appendixes simple drainage was carried out in twenty with a subsequent appendectomy in eight and conservative nonoperative treatment was instituted in five. There were thirteen, 15.9 per cent, deaths in the entire series. Nine deaths occurred in the series in which the appendix was ruptured; eight were due to general peritonitis and one to pneumonia. Two of the four deaths among the thirty-one cases without rupture were due to pneumonia, one to heart failure and one to pulmonary embolism. The type of anesthesia employed seemed to have no apparent influence on the mortality rate. In the thirty-one cases in which the appendix was unruptured there were seventeen cases with gangrenous appendix and fourteen showed varying degrees of acute purulent appendicitis. The duration of the disease was of less than twenty-four hours in twenty cases, less than forty-eight hours in eight and of more than forty-eight hours in three. The history was considered atypical in twenty of these thirty-one cases. In the fifty-one cases of ruptured appendixes there were only seventeen cases in which the duration of the disease was forty-eight hours or less. General peritonitis was present in twenty-nine patients, abscess formation in eleven, gangrenous appendix and some degree of localizing peritonitis in seven. The

history in at least thirty of these fifty-one patients was considered atypical. The symptoms were atypical in that they simulated intestinal obstruction and carcinoma. Any patient in this age group in whom lower abdominal cramplike pains develop with localization and tenderness over McBurney's point and with a leukocytosis must be suspected of having acute appendicitis. The peritoneum and the appendix of a patient in the late decades react differently to inflammation than in youth. The appendix shows an increasing amount of lymphoid tissue up to the age of 20, but from this period on atrophic and fibrous changes occur. The sensitivity of these people to pain is less and psychologically they are inclined to conceal illness. The presence of constipation in a large percentage of these patients seems significant. The appendicitis in many of these cases could be explained on these factors with a certain degree of appendical obstruction by fecaliths, anatomic appendical deformity, adhesive bands, contraction of the mesentery and the like. When obstructing factors are present and there is an already retarded circulation, with a decreased tissue resistance due to the disappearance of the lymphoid elements, it seems reasonable that the course of the disease should be rapid with early gangrene, perforation and peritonitis. Operation in this group must be modified to a certain extent. Not only is the patient a poor operative risk demanding the minimum of manipulation and anesthesia, but the appendix is almost always gangrenous or about to become so. Peritonitis is usually present and further dissemination of the infection should be avoided by conservatism in surgical intervention. Often simple drainage without further exploratory measures will bring about the best results.

Surgical Treatment of Chronic Gastric Ulcer.—Walters and Clagett report 272 consecutive cases of chronic gastric ulcer in which operation was performed at the Mayo Clinic followed for from one to five years. There were 220 men to fifty-two women, or a ratio of about 4.5:1. The majority of the lesions developed along the lesser curvature close to the angle of the stomach. The one major complication to which gastric ulcer is but duodenal ulcer is not subject is malignant change. The authors believe all gastric ulcers must be considered malignant until proved otherwise and should be treated surgically if they fail to respond promptly to medical management. When the symptoms have been of short duration, the lesion small and uncomplicated and the patient less than 40 years of age, medical management may be indicated. If the pain is relieved, the blood disappears from the stool, and the niche, on x-ray examination, disappears, the patient may be considered to have a benign ulcer. However the patient must continue medical management at home and undergo x-ray reexamination at least every three months. If at any time there is any evidence that the lesion has not remained completely healed, surgical exploration should be advised. Surgical treatment of chronic gastric ulcer is almost always indicated if the symptoms have been of long duration or have not responded to adequate medical management. Likewise, operation may be indicated if the symptoms are severe and disabling but of short duration. Surgical intervention is indicated in cases of bleeding, perforating and obstructing gastric ulcers. Posterior Pólya resection was used for 131 of the 272 patients, knife or cautery excision of the lesion combined with gastro-enterostomy was used in fifty cases and other procedures were used much less frequently but in some cases to good advantage when resection or excision and gastro-enterostomy were not feasible. Only one patient of the 162 who answered the questionnaires classified himself as having a poor or unsatisfactory result. This patient had had a simple excision of the ulcer, a procedure which is not recommended. The results were approximately equal for all types of surgical procedures indicating that the operation be fitted to the patient. Gastro-enterostomy without excision of the gastric ulcer seemed to give the least satisfactory results. However, on some occasions no other procedure is advisable or technically feasible. There was only one case of possible bleeding following operation and no cases of gastrojejunal ulcer were definitely proved following any of the procedures performed; however, some patients in each group at times had some mild distress. Disturbing symptoms or recurrence of ulceration is seldom encountered following operation.

Syndrome of Congenital Abnormalities.—Ellis and van Creveld observed in two children the following congenital abnormalities: ectodermal dysplasia affecting the hair, teeth and nails; polydactyly, chondrodysplasia, and congenital morbus cordis. The clinical picture is so striking that they believe a description of the syndrome is justified. Many atypical cases of achondroplasia and chondro-osteodystrophy with associated abnormalities have been recorded, but no detailed description of the syndrome is to be found. Some clinical particulars of a child who is an incomplete example of the same syndrome has been reported by McIntosh in 1933. Another instance is included in the present series. The most significant points in the family history of the three cases are that the parents of two were first cousins, and in no case were any of the features of the syndrome known to have existed in relatives. This is a reliable observation, for, with the exception of congenital morbus cordis, any one of the components (ectodermal defects, chondrodysplasia and polydactyly) would have excited comment in the family. It is therefore suggested that the syndrome had been inherited as a recessive gene or genes and had reappeared on the union of two individuals both carrying the recessive character. The ectodermal dysplasia must be considered as distinct both from the anhidrotic type, which occurs as a sex linked recessive or incomplete dominant, and from hypotrichosis and dystrophy of the nails, which occurs as a dominant. Polydactyly may occur as either dominant or recessive, but true achondroplasia is probably an incomplete dominant. Possibly a linkage of recessive genes would account both for the variety of the structures involved and for the extreme rarity of the syndrome. If such were the case, one might expect to find one or more components of the syndrome appearing separately in collaterals. In addition to the Laurence-Moon-Biedl syndrome and examples of ectodermal defect linked with abnormalities of the mesoderm, conditions which excite comparison are arachnodactyly, cleidocranial dysostosis and gargoylism. Each of these conditions shows a combination of mesodermal and ectodermal defects, and it remains to be proved whether they are the result of a linkage of genes or whether a single gene is responsible.

Vitamin K for Hemorrhagic Disease of Newborn.—Kugelmass states that each case of hemorrhagic disease of the newborn differs in the cause and course but that the bleeding is invariably due to prothrombin deficiency. The mild form of this disease is undoubtedly self limited and some cases are not recognized. Two of ten cases were discovered in the course of routine clotting time determinations. Severe cases respond poorly to all forms of therapy. Waddel and Guerry reported a carefully controlled human experiment: A mother had given birth to four successive infants with fatal hemorrhagic disease confirmed by necropsy. The low prothrombin content during her fifth pregnancy was brought to normal levels by an adequate diet high in fat and protein. The fifth infant was normal and without hemorrhagic symptomatology to date. Her sixth pregnancy was characterized by a similar decrease in the prothrombin level, but she refused nutritional therapy and gave birth to an infant with severe hemorrhagic disease. During her seventh pregnancy the prothrombin level was raised by adequate diet and the infant was normal. A clear-cut case of antepartum prevention of potential hemorrhagic disease was that of an undernourished woman who had given birth to a melanic infant. Since the onset of her menstruation she had occasional nosebleeds, oozing from the gums, mild metrorrhagia and ecchymoses from

asy bruising. These manifestations cleared during a previous pregnancy and since the onset of the present pregnancy, when a low prothrombin level was correlated with a limited dietary of a food faddist, apparently deficient in vitamin K, and the vitamin also decreased by persistent colonic irrigations. Her unstable blood clotting mechanism was corrected by the administration of an extract of vitamin K with each meal and an adjusted dietary regimen. At term a normal male infant was born with no evidence of hemorrhagic manifestations. Two other cases were similarly treated with vitamin K. Vitamin K administered in two mild cases of hemorrhagic disease of the newborn cleared the condition within twenty-four hours. The spontaneous bleeding ceased more rapidly than expected of a self-limited condition. Vitamin K is thus of equal value with blood transfusion in mild cases, the one forming prothrombin and the other providing it. Mild cases of hemorrhagic disease of the newborn offer no final criteria of the curative value of vitamin K because coexisting hematogenous jaundice may diminish absorption and utilization of the vitamin and thus interfere with the synthesis of prothrombin. The ability of vitamin K to raise prothrombin levels in the blood of the newborn is no index of its efficacy in hemorrhagic disease from injury to the reticulo-endothelial system involved in the formation of prothrombin. Vitamin K is nevertheless a valuable adjuvant in the treatment of latent or active hemorrhagic disease of the newborn. Treatment should not be limited to a precursor of prothrombin when the active substance, blood, can be injected. There is no indication for the use of vitamin K in a routine manner to protect the newborn from possible hemorrhagic disease. An abnormally high prothrombin content cannot prevent blood from oozing through a damaged vascular system unless the entire circulation is clotted. The contention that the prevention of hemorrhagic disease of the newborn will diminish intracranial hemorrhage is only partially true, because the former is a disease of the blood and the latter a result of trauma to the vascular system. The relative frequencies of hemorrhagic disease and intracranial hemorrhage are about one to twenty and the two diseases are more often mutually exclusive than coexistent.

Treatment of Scabies.—Sheppard used the following procedure in the treatment of 210 cases of scabies: All of the body below the neck was painted with a 40 per cent hypotonic solution of sodium thiosulfate. This was allowed to dry for about fifteen minutes and then painted with a 5 per cent solution of hydrochloric acid. The whole procedure was repeated in two

hours and then the linen was changed. The procedure was repeated the next day. The patient was not permitted to take a bath before twelve hours after the conclusion of the second day's treatment. An interval of from three to five days was allowed to elapse before a second course of treatment was started. For children less than 7 years of age the solution used is half strength. The treatment has been rapidly and highly successful in the papular type of scabies. In the pustular type it was too irritant for comfort and the ordinary sulfur ointment treatment was used in such cases until the pustules dried up, and then the case was treated on the same lines as a papular case. Of the 210 patients treated 177 were cured and twenty-five were relieved. The advantages of the treatment are that it is relatively clean, and, except in the worst cases, hospitalization is unnecessary.

Gonococcal Vulvovaginitis in Children.—Mukherjee points out that of 1,138 cases of gonorrhea treated at the clinic 125, or 11 per cent, occurred in girls under 11 years of age. The real incidence would possibly be much lower if the infection in women were more frequently recognized. Forty of the children were treated by orthodox procedures, twenty-five with female sex hormone, fifty with estrogen and local medication and ten with sulfanilamides. The cures, relapses and failures with local treatment were respectively 66.2, 22.5 and 15 per cent, with estrogen they were 44, 32 and 24 per cent and with combined treatment they were 84, 12 and 4 per cent. Of the ten cases treated with sulfanilamide seven were cured after three weeks of treatment, two after seven weeks of treatment and one could not be followed up.

*Tetanus. L. Rouques.—p. 497.

Tetanus.—Rouques calls attention to the successful experiments with tetanus anatoxin prepared from tetanus toxin subjected to the combined action of formol and heat. This substance was observed to create and develop antitetanic immunity without local or general reactions. The therapy of tetanus is well established. It consists of early and massive administration of serum subcutaneously or intramuscularly and of anesthesia. Serum therapy, however, is solely antitoxic and has no effect on the spores that may remain in the wound. To complement the passive immunity produced by the serum with an active immunity produced by anatoxin vaccination, a mixed treatment has been recommended. This consists of injecting immediately after the diagnosis is made one massive dose of tetanus antitoxin (150,000) and a dose of 2 cc. of anatoxin, injecting further doses of anatoxin in quantities increasing in mathematical proportion, 2, 4, 6 cc. for example, five or six days apart. To avoid serious accidents the massive dose of antitoxin may be divided into several smaller doses, provided the serum is strong in antitoxin. For previously vaccinated patients with a single wound one further injection of tetanus anatoxin has been recommended. It is well to examine in every instance the place

of entry and excise possibly the cicatrix at the first symptoms of the disease. For anesthesia chloral and chloroform are used; in the presence of liver damage the chloroform is replaced by nitrous oxide or ether.

Pneumothorax in the Newborn.—Péhu and Lefebvre des Noettes review the etiology, symptoms, diagnosis, therapy and prognosis of pneumothorax, with a citation of illustrative cases from the literature and an extensive bibliography. The term "newborn" is restricted by them to the first four weeks of postnatal life. Among the causes of neonatal pneumothorax the authors list obstetric trauma; artificial stimulation of respiration; brain lesions not due to natal traumatism such as intracranial hemorrhages; obstructions in the trachea such as congenital goiter and hypertrophy of the thymus; infectious disease complications such as lobar pneumonia; accidents caused by hypodermic puncture; bronchial and cardiac malformations, and a variety of causes of undetermined origin involving fundamentally rupture of the superficial alveoli of the lungs. Pulmonary tuberculosis may be eliminated as a causative agent. Three types of neonatal pneumothorax are distinguished (partial, total, high tension) and their typical roentgenographic features indicated. Dyspnea and cyanosis, characteristic signs of pneumothorax of the newborn, need to be diagnostically differentiated from pathologic conditions such as normal neonatal cyanosis, those occurring in cardiovascular malformations, and from tracheal thymus pressure, bronchial or bronchopulmonary air cysts, pulmonary atelectasis and bronchopneumonia. In all of these, clinical and roentgenoscopic observations combine to disclose the real facts. Prognosis is favorable in pneumothorax of traumatic origin and in congenital bronchial malformation in which no pathologic signs manifest themselves. In high tension pneumothorax prognosis is likewise good, provided pleural punctures succeed in preventing recurrence of air infiltration. The authors point out that the mechanism of the physiologic function of breathing when the infant first establishes independent respiration is still imperfectly understood, no elucidating roentgenograms yet existing. These mechanical factors occupy an important place in the pathogenesis of infant pneumothorax.

*Electrocardiograms in Carbon Monoxide Poisoning. G. Rastelli.—p. 533.
Relations Between Heart Diseases and Pulmonary Tuberculosis. F. Robuschi.—p. 587.

Electrocardiograms in Carbon Monoxide Poisoning.—Rastelli studied electrocardiograms of two lots of rabbits before and in the course of acute and chronic experimental carbon monoxide poisoning, and those of forty-two victims. Typical transient modifications of the ventricular complex were present in the electrocardiograms of rabbits with acute poisoning. The alterations of the electrocardiogram in acute poisoning in man, shortly after the occurrence of poisoning, consisted of a low potential action of the myocardium, auricular fibrillation, premature ventricular contraction and predominance of the left ventricle. The electrocardiograms of victims of acute poisoning became normal, in the majority of cases, in about two months. Certain permanent electrocardiographic alterations remained in some of the cases. They consisted of typical triphasic initial complexes in the second and third leads. Alterations of this type remained in the electrocardiograms of five out of twenty victims of acute poisoning in whom electrocardiograms were taken at periods of from two to five years after the acute poisoning. They were present in five out of twenty victims with chronic carbon monoxide poisoning. These alterations were of a type which, according to Katz and Slater, indicate damage to the coronary arteries. The author concludes that carbon monoxide poisoning causes either transient or permanent lesions

in the heart with consequent transient or permanent alterations in the electrocardiogram. Transient lesions are caused by anoxemia due to poisoning, whereas permanent lesions are the result of damage to the endothelial lining of the coronary arteries, as carbon monoxide has a specific injurious effect on the epithelium of the arteries.

Constitution of Adventitia Capsule of Echinococcus in Relation to Seat of Echinococcosis. A. Ligas.—p. 188.

Histology of Some Renal Tumors.—Ciancarelli discusses the question of the epithelial or adrenal origin (Grawitz) of renal tumors, particularly of hypernephroma, based on a study of four renal tumors removed by nephrectomy. The microscopic diagnosis was hypernephroma in two and papillary adenocarcinoma in two. The two patients with hypernephroma did not exhibit symptoms of endocrine disturbance, and one gave a negative Aschheim-Zondek reaction. The tumor was located in the upper pole of the kidney in one case and in the lower lobe in the other. The author found that the microscopic structure of hypernephroma and of papillary adenocarcinoma was similar. Cells with either clear or dark protoplasm were present in both tumors. The microscopic preparations of hypernephroma in one of the cases showed tubular structures of the type present in adenocarcinoma. Adrenal tumors do not present tubular structures. He believes that papillary adenocarcinoma and hypernephroma are of the same renal epithelial origin and that hypernephroma is nothing more than a variety of a renal epithelioma. The name "hypernephroma" possesses no histogenic significance. The theory of adrenal origin of hypernephroma (embryonal aberrant adrenal tissue, according to Grawitz) is based on an erroneous interpretation of the microscopic appearances of the tumor cells. The latter are more or less loaded with fat because of fatty degeneration from nephritis and may assume an appearance similar to that of adrenal cells.

Vitamin C and Gastric Function.—Regarding disordered gastric function as the cause of pellagra, Lucksch treated pellagral patients with a preparation of hog stomach. The same preparation was given also to schizophrenic and encephalitic patients with a deficiency of hydrochloric acid. It was found that the secretion of hydrochloric acid was stimulated by this medication and that the symptoms of pellagra subsided. Vitamin C also had been found helpful for pellagrous patients, but at the time this was first noted it was impossible to investigate the gastric secretion. Later the author investigated the effect of vitamin C, vitamin B, liver, liver preparations and hydrochloric acid pepsin on the gastric secretion of patients with hydrochloric acid deficiency. The hydrochloric acid pepsin was entirely ineffective. The effect of the vitamin B preparation was somewhat doubtful, but the vitamin C proved highly effective. The author points out that this action of vitamin C on the deficiency of hydrochloric acid is a new discovery, for although the literature reports favorable effects of vitamin C on hyperacidity there are no reports on its efficacy in hypo-acidity. This action of vitamin C can probably be explained by the fact that it is a substance which stimulates the entire metabolism and thus also the organs with functional insufficiency. The author suggests that it might be advisable to give vitamin C in pernicious anemia in addition to liver therapy. These experiments raise the question whether parenterally administered vitamin C acts as a substitute for its insufficient enteral absorption in pellagra or whether its curative action is due chiefly to the restoration of the gastric function.

ORTHOSTATIC HYPERTENSION

THE EFFECT OF NEPHROPTOSIS ON THE
RENAL BLOOD FLOW

CHAIRMAN'S ADDRESS

WILLIAM S. McCANN, M.D.

WITH THE COLLABORATION OF
MONROE J. ROMANSKY, M.D.

ROCHESTER, N. Y.

In the light of the observations of Goldblatt¹ that partial ischemia of the kidneys produced hypertension in experimental animals, many clinical and pathologic observations have been made illustrative of a variety of conditions in which renal ischemia occurs in association with elevation of blood pressure. Atheroma at or near the aortic orifice of the main renal vessels appears to be one of the most frequent;² pyelonephritis, glomerulonephritis and a variety of urologic conditions involving urinary obstruction have been described.³

The observation of marked ptosis of the kidneys of a woman who had exhibited what was taken to be a benign essential hypertension for a number of years and who entered a malignant phase of the disease with eclamptic phenomena and evidence of cerebral and neuroretinal edema raised the question as to whether the ptosis, by increasing ischemia of the kidneys, might have been responsible for the transformation from a benign to a malignant hypertension.⁴ In the search for the answer to this question a number of women with hypertension and renal ptosis were found whose blood pressure fell when they were kept strictly in a recumbent posture, either to normal or to levels distinctly below the usual range of blood pressure observed when they were not confined strictly to this posture. Some of these patients have been studied by means of pyelograms made in both the erect and the recumbent posture to reveal the degree of ptosis of the kidneys and subsequently by comparing the effects of posture on the inulin clearance (glomerular filtration rate) and on the diodrast clearance (total renal plasma flow).

Dr. Romansky is the James Gleason Fellow in Medicine.

Read before the Section on Practice of Medicine at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

From the Department of Medicine, University of Rochester School of Medicine and Dentistry, and the Medical Clinics of the Strong Memorial and Rochester Municipal hospitals.

4. McCann, W. S.: Chronic Pyelonephritis: A Cause of Hypertension and Renal Insufficiency, *New York State J. Med.* **40**: 400 (March 15) 1940.

The method employed was based on the work of Homer Smith and his colleagues⁵ and on the technic of White and Rolf for microdetermination of diodrast.⁶ By means of intravenous priming and sustaining solutions of inulin and diodrast in 1 per cent saline solution, which were introduced simultaneously, the desired blood levels of from 100 to 150 mg. per hundred cubic centimeters of inulin and from 0.5 to 5 mg. per hundred cubic centimeters of diodrast could be maintained.

Tests were made on fasting patients in both the erect and the recumbent position. In the former position the test was usually carried out first with the blood pressure maintained at its high ambulatory level. Then, following a period of recumbency of about two to five days, during which the blood pressure fell to a constant level, the test was repeated.

From 1,000 to 1,500 cc. of water was administered orally before each test and not more than from 150 to 200 cc. of water was given during the procedure. The entire test ran for ninety minutes, with the last hour divided into four fifteen minute periods for the collection of blood and urine specimens. From these specimens the glomerular filtration and total blood flow were determined. In the calculations the plasma clearance of diodrast is determined and the total blood flow estimated by adding the volume of red cells shown by the hematocrit.

ABSTRACT OF CASES

CASE 1.—R. H., a woman aged 56, was known to have had hypertension for twenty years. She had no urinary symptoms except that many years before she had experienced burning and frequency of urination. Within the past year cerebral and ocular symptoms had become more severe, and recently several mild hypertensive crises had occurred. Examination revealed marked ptosis of the right kidney.

In figure 1 are shown the tracings of the pyelograms made in both the erect and the recumbent posture, superimposed. Ptosis was more marked on the right side and a moderate hydronephrosis was revealed. It will be noted that the total blood flow was markedly less in the erect than in the recumbent position and that a marked difference in blood pressure levels was observed, being lower in recumbency. The change in glomerular filtration was not large, being slightly lower in recumbency. The filtration fraction was distinctly higher in the erect posture, a fact which may be taken as evidence that the efferent arterioles were constricted and that this was a major factor in the diminution of blood flow observed.⁷

Figure 2 records the daily blood pressure variations during the period of observation in the hospital. The pressure on admission was 240 systolic, 120 diastolic, which is distinctly higher than that observed on the day of the test in the erect posture, which followed a period of rest in bed. It is likely

that the record would have shown an even more striking difference if the test in the erect posture had been made during customary ambulatory activity.

Oct. 31, 1939, the right kidney was exposed by Dr. W. W. Scott in order to perform a nephropexy. An aberrant vessel was found entering the upper pole of the right kidney. This

Fig. 1 (case 1).—Tracings of the retrograde pyelograms superimposed, showing ptosis and moderate hydronephrosis of the right kidney and comparison of the total blood flow, filtration rate and blood pressure in both the erect and the recumbent posture.

was divided and found to be markedly sclerotic. Nephropexy was performed. Following this operation the blood pressure remained elevated. On December 6 it was still high, 204 systolic, 110 diastolic. Prior to entry into the hospital the blood pressure had risen frequently to critical heights (from 240 to 260),

during which episodes cardiac, cerebral and ocular symptoms occurred. Since operation these episodes have not occurred and the patient has been symptomatically improved. The persistence of elevation of the blood pressure may be explained by the sclerotic condition of the renal arteries observed in the aberrant vessel and may have been in part due to the further increase in

renal ischemia resulting from the division of this vessel. The latter possibility is further suggested by the fact that strict limitation to recumbency prior to operation brought the blood pressure as low as 138 systolic, 88 diastolic on October 4. Recently the blood pressure has been decreasing slowly.

CASE 2.—R. W., an unmarried woman aged 22, was known to have had hypertension for eight years. Her only symptom was frequency of urination, five or six times daily. There was no nocturia. Pyelograms revealed ptosis and torsion of the left kidney.

In figure 3 are shown the superimposed tracings of the retrograde pyelograms. The total blood flow was considerably less in the erect posture and the blood pressure higher than in recumbency. The glomerular filtration rate was also higher in recumbency, yet the filtration fraction was higher in the erect posture.

Observations of the blood pressure during ambulatory activities were usually about 185 systolic, 120 diastolic. In figure 4 are shown the daily observations of the maximum and minimum ranges of the systolic and diastolic pressures. It will be noted that the blood pressure fell steadily during four days of rest in bed and rose sharply on the fifth day when she was allowed to be up, again falling when confined to bed in strict recumbency.

CASE 3.—R. L., a woman aged 31, had been known to have hypertension for ten years following a late toxemia of pregnancy. Intravenous pyelograms revealed considerable ptosis of the right kidney.

Figure 5 shows the superimposed tracings of kidney shadows. The total blood flow was less in the erect posture and the blood pressure was higher, and the filtration fraction increased from 20 per cent in recumbency to 30 per cent when erect. In the outpatient clinic her usual blood pressure was about

Fig. 2 (case 1).—Daily observations of the maximal and minimal systolic and diastolic blood pressure.

180-200 systolic, 100-120 diastolic. In figure 6 are shown the daily blood pressure variations. It is probable that the differences in the tests would have been more striking if the tests in the erect posture had been carried out in the outpatient department. Efforts to correct the ptosis by means of a belt with a pad were not successful in bringing a return to normal blood pressure. Nevertheless the patient did experience symptomatic relief.

CASE 5.—H. B., a married woman aged 47, had probably had onset of hypertension in her first pregnancy twenty years before, when she had a marked urinary infection. Cerebral and ocular

Fig. 3 (case 2).—Tracings of the retrograde pyelograms superimposed, showing ptosis and rotation of the left kidney, with comparison of the total blood flow, glomerular filtration and blood pressure in the erect and with those in the recumbent posture.

symptoms had increased in severity during the past four years. Periodically alternating oliguria and polyuria were noted. The urine had been sterile on culture before operation, though the sediment contained an excessive number of leukocytes. Renal function as measured by the phenolsulfonphthalein test was found to be quite good.

In figure 9 are shown tracings of the retrograde pyelograms in both postures. There was found to be marked ptosis on the right with dilatation of the ureter and some deformity of the pelvis. A moderate fall in blood pressure with an increase in blood flow was noted in the recumbent posture. Very little change in glomerular filtration occurred, although the filtration fraction was greater in the erect posture.

An operation for nephropexy was performed on the right kidney, which was subsequently complicated by the appearance of a large mass in the right side of the abdomen. This was believed to be a hematoma, since it gradually disappeared. Following operation, culture of the urine was persistently positive for *Escherichia coli* and the blood pressure remained elevated, though the patient experienced much less headache and less visual disturbance, and cardiac symptoms were less marked.

In figure 10 are shown the day to day observations of the blood pressure before operation. It will be noted that rest in bed had little effect on the blood pressure. It is probable that the hypertension is chiefly to be attributed to long-standing pyelonephritis and accompanying vascular sclerosis, to which the ptosis added but an increment to an underlying renal ischemia.

Fig. 4 (case 2).—Daily observations of the maximal and minimal systolic and diastolic blood pressure.

In view of the failure of nephropexy to give relief of the hypertension, patient 5 is to be observed again for review of the urologic condition for the purpose of determining whether a right nephrectomy is advisable. The decision will depend on the relative function of the two kidneys and on a determination as to whether or not the left kidney is also the seat of a chronic pyelonephritis.

COMMENT

In table 1 are recorded the observations on five patients with nephroptosis, and in table 2 those on five controls with normal blood pressure and on two patients

Fig. 5 (case 3).—Tracings of the superimposed renal shadows in roentgenograms, with the total blood flow, glomerular filtration and blood pressure in the erect and in the recumbent posture.

with hypertension. In none of the control cases was there an appreciable degree of nephroptosis.

When the two groups are compared it is readily apparent that change of posture produced significant effects on the renal blood flow and blood pressure of those who had nephroptosis as against those who had

not. Among the patients with nephroptosis (table 1), in each instance the blood pressure was higher in the erect posture. Among the controls only one person (M. D.) showed an increase of 21 mm. in systolic pressure and a decrease of 5 mm. in diastolic pressure on assuming the erect posture. The remaining controls showed insignificant change in systolic pressure, though F. H., a hypertensive patient, had a rise of 20 mm. in diastolic pressure when erect. We shall refer hereafter to the elevation of blood pressure in the erect posture observed in patients with nephroptosis as an "orthostatic hypertension."

Among these patients (table 1) it was observed that the total renal blood flow, as measured by means of the plasma diodrast clearance and the hematocrit, was in

Fig. 6 (case 3).—Day to day variations in the blood pressure as affected by posture and activity.

each instance less in the erect than in the recumbent posture, the decrease ranging from 20.5 to 43.5 per cent of the recumbent flow. Goldblatt has observed that slight degrees of partial renal ischemia are capable of

in contrast to a rather striking constancy in the control observations. The "filtration fraction" represents the ratio of the glomerular filtration (inulin clearance) to the total plasma flow (diodrast clearance). Homer

Fig. 7 (case 4).—Tracings of the kidney shadows superimposed after intravenous pyelography, with a comparison of the total blood flow, glomerular filtration rate and blood pressure in the erect and with those in the recumbent posture.

Smith⁷ has shown that the vasomotor activity within the kidney is such that constriction and dilatation of the efferent glomerular arteriole provides the usual control of renal blood flow except when the cardiac output is markedly influenced by extrarenal factors. Smith has good reason to believe that constriction of the vasa efferentia increases the pressure in the glomeruli and in this manner maintains the rate of glomerular filtration nearly constant while diminishing the volume of

exciting the pressor mechanism by which blood pressure is elevated. It is not unreasonable, therefore, to attribute the instances of orthostatic hypertension which we have observed to the diminished blood flow through the kidneys in the erect posture.

Significant changes were also observed in the "filtration fraction," which was increased in each instance of orthostatic hypertension in the erect posture (table 1),

plasma flowing through them. In this way a diminished blood flow is compensated by the filtration of a greater fraction of the plasma into Bowman's capsule. The clearance ratio of diodrast to inulin in all cases (table 1) increased in the change from the erect to the recumbent posture.

The effect of the pressor substance "renin" on the intrinsic circulation of the kidney has been studied by

Merrill, Williams and Harrison.⁸ When renin elevated the blood pressure of an experimental animal the kidney was observed to swell, its blood flow diminished and its output of urine increased. These observations are in consonance with those of Smith and point to a constriction of the vasa efferentia.

In the light of these facts, one may postulate the following events in cases of nephroptosis exhibiting orthostatic hypertension: 1. The erect posture causes some slight interference with the afferent blood supply in consequence of which renin is produced. 2. The action of renin results in constriction of the vasa efferentia in both kidneys with the result that the total renal blood flow is still further decreased, while at the same time the glomerular filtration remains relatively constant, owing to the compensatory effect of increased intraglomerular pressure.

It should be stated that nephroptosis does not always result in hypertension. The cases reported here were selected because of the association of hypertension with ptosis of the kidneys. We have as yet no basis for estimating the frequency with which this factor operates to produce an orthostatic elevation of the pressure.

Fig. 8 (case 4).—Day to day variations in the blood pressure as affected by posture and activity.

It is worth while to remember that hypertension is much more frequent among women than among men and that nephroptosis is very common among women.

The therapeutic efforts applied in our cases have not yielded very striking results. In case 1 hypertension was not relieved by nephropexy. Its persistence may have been due to ligation of an aberrant vessel, thus creating a new factor of renal ischemia. Extirpation of the kidney in this case might possibly have relieved the hypertension, though it is probable that there was considerable sclerosis of the arteries of the other kidney, which might have caused failure in any case.

In cases 1 and 5, in which hypertension persisted, there was nevertheless considerable relief of symptoms following nephropexy, as was also true in case 3, in which a ptosis belt was worn. The support given to the kidneys seems to have prevented the critical orthostatic exacerbations of blood pressure and attendant cerebral, ocular and cardiac symptoms.

In view of these observations it would appear to be desirable to ascertain the effect of posture on the blood pressure of all hypertensive patients. Those in whom the pressure falls markedly when confined strictly to the

recumbent posture deserve urologic study and some sort of support to the kidneys if ptosis is found. An important point to be stressed in testing for the effect of posture is that recumbency must be maintained through-

Fig. 9 (case 5).—Superimposed tracings of the retrograde pyelograms showing evidence of ptosis and chronic pyelonephritis of the right kidney and to a lesser degree of the left. Comparisons are made of the total blood flow, glomerular filtration and blood pressure in the erect and with those in the recumbent posture.

out the test. The patient should not get up out of bed or even sit up while the test is in progress, since these changes may excite the pressor activity with results lasting for several hours.

Fig. 10. (case 5).—Day to day observations of the blood pressure.

CONCLUSIONS

1. In some instances of nephroptosis the erect posture may result in orthostatic elevation of the blood pressure, with diminution of the total renal blood flow and with relative constancy of glomerular filtration, though the "filtration fraction" is increased. The clearance ratio of diodrast to inulin is decreased in the erect as compared with that in the recumbent posture.

2. Patients with normal blood pressure and those with hypertension but without nephropotosis did not exhibit these changes.

3. Hypertensive patients should be studied with regard to the effect of posture on the blood pressure by comparing the pressure during ordinary activity with that found after a period of strict recumbency. Those in whom a marked orthostatic effect is demonstrated should receive pyelographic study and treatment by appropriate support of the kidneys which are ptosed. Cerebral, ocular and cardiac symptoms may be relieved by the stabilization of blood pressure which results from such measures.

SYPHILIS OF THE STOMACH

CARRINGTON WILLIAMS, M.D.

AND

PAUL KIMMELSTIEL, M.D.

RICHMOND, VA.

In past years eight cases of syphilis of the stomach and two cases of syphilis of the colon have been reported from this clinic (LaRoque,¹ Pusch,² Williams³). We feel perfectly confident of the diagnosis of these cases and feel that they present the classic picture of advanced syphilitic involvement. We find, however, that there is wide divergence of opinion, from the view that the lesion is actually not syphilitic in nature to that of reporting nonspecific ulcers in a syphilitic individual as examples of this disease. The occurrence of another typical case prompts us to review our former experience and to present the subject particularly from the standpoint of diagnosis, microscopic appearance of the lesion, and treatment.

In the first place we would emphasize the point that the lesion which we are discussing is an infiltrating one which involves varying amounts of the stomach and is located primarily in the submucosa. From this location varying amounts of mucosa and muscularis are involved and ulceration is secondary and, therefore, usually shallow. In all of our cases the location has been in the pylorus. Pusch⁴ states that in 86 per cent of a group of thirty-five cases selected by him from the literature on the basis of authenticity the lesion was located in the pylorus. This is important from the standpoint both of diagnosis and of treatment. The next most frequent location is the midstomach, where an hour glass deformity is produced (Mayer⁵). When the disease has existed for a long time the entire organ may be involved, producing a leather bottle deformity (Cabot Case Records⁶). This gradual infiltration into a large part or all of the stomach is an important one to have in mind when deciding the method of treatment.

It must be admitted that the diagnosis can positively be made only after long continued successful anti-

syphilitic therapy or by the gross appearance and microscopic picture of removed tissue.

These patients usually present themselves with history of a severe stomach disorder often typical of cancer. Pain, weight loss and vomiting are prominent symptoms. Physical examination may reveal nothing specific but occasionally an epigastric mass is found and not infrequently other stigmas of syphilis are present. The Wassermann reaction is almost always positive. Gastric analysis usually reveals achlorhydria. There is often secondary anemia, and occasionally massive hemorrhages result in profound acute anemia (LaRoque¹). Gastroscopic examination has apparently been done in few cases. Carey and Ylvisaker⁷ report a case in which the stomach was markedly contracted and the mucous membrane pale.

As in all stomach lesions the x-ray appearance is the most important diagnostic sign. Most authors say that this appearance is indistinguishable from cancer. Downes and Lewald⁸ in 1915 suggested certain typical appearances in syphilis as contrasted with cancer. One of us⁹ emphasized the smooth tubelike or funnel deformity as characteristic of syphilis. Obviously one cannot be certain of the diagnosis on the basis of the clinical picture and x-ray appearances, but they are highly suggestive.

The gross appearance of the lesion has been well described by Meyer and Singer,¹⁰ who have had an unusually large experience with this disease. They emphasize the fact that the gross appearance of the lesion is much less extensive than the x-ray appearance. In cancer the opposite is usually found. In early cases the stomach is pliable where x-ray examination showed a gross deformity. Later it has a tough but smooth feel. There may be edema. The lymph glands are often involved; they are usually soft and may be gray or pink.

On cross section of the wall the submucosa mainly is involved in the process of infiltration, although the muscularis likewise appears thicker than normal. The mucosa covering the involved area is dull and smooth; it may show small shallow ulcers or the whole may have ulcerated from the involved portion in an annular fashion.

The microscopic appearances are so important in establishing a diagnosis of syphilis of the stomach that we will give them in some detail and discuss other opinions from the literature.

Histologic sections reveal a more or less diffuse infiltration of the entire wall with a variety of round cells, predominatingly lymphocytes and plasma cells. The infiltration is most marked in the submucosa but penetrates within the intermuscular connective tissue, the muscularis proper, and appears in the serosal tissues. A conspicuous perivascular arrangement of this inflammatory infiltration is noticeable. In some cases true gummas or small gummoid nodules are seen composed of epithelioid cells with occasional multinucleated giant cells. Vascular lesions are described as an outstanding characteristic feature. Proliferating endarteritis is most commonly found and frequently referred to as one of the outstanding histologic criteria. Less frequently noticed, but in our opinion of more

value in regard to the differential diagnosis, is the panphlebitis. This lesion is more often found than endarteritis but can be detected only with special stains for elastic fibers. The mucosal ulcer is nonspecific in appearance. At its floor, which is composed of dense granulation tissue undergoing necrobiosis, vascular lesions are particularly prominent. Endarteritis of large arteries and necrosis with thrombotic occlusion of small vessels are often encountered. These vascular lesions, however, are of the same nature as found in nonspecific peptic gastric ulcers.

None of the aforementioned criteria alone are pathognomonic, but in connection with the clinical and serologic data they may be used as collective evidence.

Reviewing the literature on this subject, it occurred to us that the phlebitis, as one of the outstanding criteria in aid for differential diagnosis, has not found the attention it deserves. Only a few authors mention its occurrence. The first to describe this lesion was E. Fraenkel¹¹ in 1898. It is furthermore described by Kwartin and Heyd,¹² Konjetzny¹³ and Singer.¹⁴ This author in two papers stresses the significance of panphlebitis, pointing out that the veins in comparison to the arteries bear the brunt of injury and also warns that a special stain for elastic fibers is necessary to demonstrate the lesion.

It is apparently for this reason that the severe involvement of veins has been so often overlooked. In such cases in which definite absence of endophlebitis was reported (McNee¹⁵) there is no mention of elastic tissue stain being applied.

The type of phlebitis referred to in this connection in reality is not a primary manifestation of syphilis in the vascular system but is invariably secondary in nature. As such, however, it is indicative of the destructive character of the syphilitic granulation tissue in which it is involved. Diffuse syphilitic granulation tissue, which is known to spread in perivascular lymph spaces, penetrates the adventitia and the medial coat of the veins, destroys its connective tissue and muscle fibers, splits up the more resistant elastic fibers and finally enters the lumen, which it may completely obliterate. It is obvious that in the late stages the original structure of the venous wall cannot be recognized in regular hematoxylin and eosin stained sections, though elastic tissue stain will demonstrate its outline. It is often noticeable and indeed striking to find the completely destroyed veins next to entirely intact arteries.

We refer to this type of panphlebitis as periendophlebitis, indicating the direction of progress of the granulation tissue penetrating the wall of veins from outside in, thus distinguishing it from other types of phlebitis primarily beginning in the vascular coats proper. A distinction should be made between the obliteration of the venous lumen by penetrating granulation tissue and an occlusion due to proliferation of endothelial and subendothelial elements which may be encountered in such segments of the vein in which the adventitia is involved in perivenous inflammatory granu-

lation. The latter type of endophlebitis does not bear specific significance. It is not easy to state just how much weight the demonstration of true periendophlebitis carries as a morphologic criterion for the diagnosis of syphilis. However, we have found it to be exceedingly helpful in establishing the specific etiology of granulation tissue. It is found to be far more indicative than, for instance, the predominatingly perivascular arrangement of lymphocytic and plasma cellular infiltration. Proliferating endophlebitis alone is likewise considered to be nonspecific and we agree with Konjetzny¹³ that it is frequently found in simple peptic ulcers of the stomach.

Destruction of veins in syphilitic granulation tissue is found in all three phases of syphilis and in all organs (Benda¹⁶). In tertiary syphilis, however, it seems to occur with particular frequency in the gastrointestinal tract (Fahr,¹⁷ Rieder,¹⁸ Fraenkel,¹¹ Gatewood¹⁹).

We have found periendophlebitis in all the specimens diagnosed as syphilis of the gastrointestinal tract examined in our laboratory. Wohlwill²⁰ considers this lesion an important aid in differential diagnosis of

Fig. 1.—Low power field showing one artery with intact wall and some endarteritis. Next to it, medium sized vein with intact wall and endophlebitis. A larger vein, the wall and lumen of which are diffusely infiltrated by granulation tissue, the elastic lamellae being partially destroyed. Elastic tissue stain.

syphilis of the kidney. We have seen it without and in conjunction with gumma formation in every organ (testis, kidney, thyroid, heart) but we were unable to demonstrate it satisfactorily in four cases of syphilis of the lung (figs. 1 and 2).

Periendophlebitis, though indicative of syphilitic granulation tissue, is not pathognomonic. It is occasionally noticed in other types of specific infiltrating granulation tissues (particularly venereal lymphogranuloma). If this venous lesion is taken merely as a manifestation of an extraordinarily destructive nature of a chronic granulation tissue, it is a valuable participant in the collective evidence for the diagnosis of syphilis.

Finally the diagnosis was definitely proved by Harris and Morgan,²¹ who produced a chancre of the testicle in

of them are known to have remained well, one is said to have died from gastric hemorrhage, and two have been lost.

CONCLUSION

1. The syphilitic origin of this lesion has been adequately proved by gross and microscopic study of removed tissue and the recovery of *Spirochaeta pallida* from a patient by Harris and Morgan.

2. It is a clinical entity and the result of infiltration of the submucosa in the third stage of syphilis and should not be confused with a penetrating ulcer in a syphilitic individual.

3. The diagnosis cannot be positively made before operation except by long successful antisymphilitic treatment. It should be strongly suspected, however, when a comparatively young individual is found by x-ray examination to have a smooth funnel or tubelike deformity of the stomach and other stigmas of syphilis. The diagnosis is confirmed by microscopic examination and we emphasize the constant presence of periendophlebitis, which often destroys all of the vein wall except the elastic tissue.

4. Medical treatment is indicated in early cases but the disease is usually not discovered until the lesion is extensive and complications such as hemorrhage and pyloric obstruction have occurred; then resection of the involved portion of the stomach is the treatment of choice.

816 West Franklin Street.

ABSTRACT OF DISCUSSION

DR. KARL A. MEYER, Chicago: The paper of Drs. Williams and Kimmestiel is timely because of the apparent increased incidence of syphilis of the stomach. Since no cases of syphilis of the colon have been encountered in our clinic, I will restrict my discussion to gastric syphilis. It has been my good fortune to see quite a number of these cases. I agree with the authors in regard to the site of the syphilitic lesion. In the majority of our cases the involvement was in the pylorus. In only two cases was the pars media involved and in two others the entire stomach was affected, presenting the picture of a linitis plastica. The authors have rightly stressed pain, vomiting and loss of weight as the outstanding symptoms of gastric syphilis if occurring in a young individual with a positive serologic reaction. Notwithstanding the severe vomiting these patients rarely complain of nausea, since the emesis is merely a manifestation of decreased stomach capacity. It is this gradual decrease in the gastric capacity in an apparently otherwise normal individual which leads to sitophobia, severe vomiting and marked emaciation. In our series epigastric masses were palpable in only about 12 per cent of the cases. Achlorhydria was present in all of them. Other stigmas of syphilis were not especially important. In most of our cases a moderate secondary anemia was present, but we have not encountered any severe bleeding, such as hematemesis or tarry stools. Indeed, from our experience and from reports in the literature, profuse gastric hemorrhage seems to be an exceptionally rare symptom in syphilis of the stomach. Our experience with gastroscopy in syphilis of the stomach is too limited to justify any conclusions. The authors correctly stressed the difficulty in diagnosing gastric syphilis clinically. I believe that if a patient is below the carcinoma age, has a positive Wassermann reaction, has the triad of pain, vomiting and loss of weight, and x-ray appearances of extensive pathologic change in the stomach not corresponding to his general condition, he should be classed as having gastric syphilis until the condition has been proved otherwise. The roentgenogram cannot and should not be a deciding factor in the diagnosis of this condition. The therapeutic test is of definite diagnostic value and should be attempted in all cases in which surgical intervention is not urgent. We were often able to diagnose gastric syphilis at operation when we encountered a stomach

with a rather thick, boggy, hyperemic wall which was quite pliable in areas where marked infiltration should have been present according to the x-ray appearance. This is in contrast to gastric carcinoma, in which the conditions found at operation are more extensive than the x-ray examination would lead one to believe. In gastric syphilis we rarely found perigastric adhesions, and the neighboring lymph glands were usually soft and only slightly enlarged.

TECHNIC AND RESULTS IN PERINEAL PROSTATECTOMY

EDWIN DAVIS, M.D.

OMAHA

The . . . pursuit of an unattainable perfection . . . is what alone gives a meaning to our lives. . . .

—Logan Pearsall Smith.

Whether perfection is attainable in any field of human endeavor is perhaps debatable. There is no question, however, that the foregoing dictum is peculiarly appropriate as applied to surgery. Were proof of surgical imperfection necessary, the following text would suffice—as would any set of surgical statistics, honestly compiled. The elusiveness of perfection, however, is no contraindication to a persistent quest for near perfection or to an attempt to approach the ultimate goal, which, in any surgical field, is the attainment of excellence and permanence of functional results, with minimum hazard.

It is my purpose to refer briefly to certain factors tending to improve the technic of perineal prostatectomy and to present a tabulation of late functional results, based on an analysis of questionnaire replies received from 100 consecutive patients.

TECHNIC

In that Young's¹ classic description of the fundamental principles of the technic of perineal prostatectomy is readily available and is not to be duplicated (much less to be improved on), a detailed discussion of technic would here be purposeless. This subject may therefore be disposed of with brief reference to certain factors such as sacral block anesthesia,² wound antisepsis,³ hemostasis and plastic closure, which tend to eliminate postoperative complications and to minimize the mortality rate. The indispensability of preliminary drainage is too well recognized to require discussion.

Few realize that perineal prostatectomy need not be performed as a blind enucleation through a hemorrhagic field, as ordinarily supposed, but may be made a procedure permitting complete visualization throughout, with resulting precision of manipulation. After anatomic exposure without injury to the rectal wall or external sphincter, and after enucleation of the hypertrophied lobes through an inverted V incision in the posterior prostatic capsule, the perineal hemostatic drainage bag,⁴ introduced into the bladder through the urethra, then serves as a tractor to bring the bladder

"neck" and the tissues of the floor of the bladder into view. The several arterial spurters usually present, having been thus visualized and made accessible, may then easily be controlled precisely and accurately by suture ligation. Continuing to use the bag as a tractor, and with a urethral catheter in place, it is then possible to carry out plastic closure of the tissues of the prostatic capsule and bladder neck and floor in such a manner as to control venous ooze and obliterate dead space, yet leaving a gap through which the collapsed bag may be slipped out after a forty-eight hour interval. It is important to note that the temporary presence of the hemostatic bag does not retard wound healing, in that the average period for cessation of perineal urinary drainage has been reduced from twenty-one to sixteen and a half days since the adoption of a new technic including the introduction of a urethral catheter at operation. This figure, although based on only the last thirty cases, compares favorably with the average period of wound closure reported by Hinman⁵ following plastic closure with a urethral catheter in position but no hemostatic bag. With the employment of this technic, and by strict adherence to the principles of preliminary drainage, it has been possible to maintain a 2.7 per cent mortality rate in a perineal prostatectomy series now totaling 831 consecutive cases, all under sacral block anesthesia.

RESULTS

Second in importance only to mortality rate and from some points of view of even greater importance than mortality rate, is the matter of late functional results, in that the interest of most of those in the late twilight of life lies primarily in comfort. Hence the futility of saving a life not worth living (from the point of view of the patient himself) by reason of continued suffering. This opinion, although not universally held, is shared by many patients, relatives and surgeons alike.

With respect to prostatic surgery it may be stated that results may be best evaluated by the degree of postoperative urinary frequency, both by day and by night, and more particularly by the patient's own opinion as to whether he has or has not obtained complete symptomatic relief. The patient who passes urine at normal intervals without discomfort, and who reports himself as being wholly satisfied, may conservatively be classed as cured. The following simple questionnaire was worded with these criteria in mind:

1. Is the wound entirely healed?
2. Can you control the urine?
3. Do you pass urine too often?
4. How many times do you get up at night to urinate?
5. Does the urine pass without difficulty?
6. As far as the operation is concerned, do you consider yourself (1) well, (2) improved or (3) unimproved?

It is to be recognized that complete satisfaction in all cases is not to be expected, in that prostatic surgery is often (if not usually) performed after months or years of urinary tract obstruction and infection, and in the presence of coexisting old age lesions. Restoration to normal with complete disappearance of symptoms is therefore impossible in many instances, even though the purpose of the operation in relieving mechanical urinary tract obstruction has been accomplished. The tabulation here presented, showing results of analysis of 100 consecutive questionnaire replies, requires but little discussion or explanation.

The postoperative incontinence hazard is to be reckoned with following the removal of prostatic obstruction by any of the three recognized methods. Those with experience know that a careful and honest analysis of a large suprapubic prostatectomy series will show a small percentage of patients defective in this respect. Although no one denies the danger of damage to the external sphincter inherent in perineal prostatectomy, the occurrence of this complication following suprapubic prostatectomy indicates that the occasional case of unsatisfactory urinary control may result from weakness of the fibers of the external sphincter, inherent in the individual, or possibly from a coexisting central nervous system lesion. In that this comparatively small follow-up series, consisting of only 100 replies, happened to include two cases of real incontinence (one complete and one partial), percentage figures based only on this small group would have been misleading. * Excluding the two fistula cases requiring closure.

this reason a larger but similar questionnaire series previously reported⁶ has been added to the small group, bringing the total up to 353 replies and thus presenting a more accurate cross section. The totally incontinent patient included in the small group reported that he "passes urine all the time involuntarily," while those classed as partially incontinent have "some control." Those slightly incontinent or doubtful made such comments as "not full control when I cough or sneeze," "control fair" and "not entirely." Since the majority of the patients tabulated as slightly incontinent have voluntarily classified themselves as "well," it is evident that this defect is not the source of a great deal of annoyance.

By reason of persistent slight perineal urinary drainage, two of these patients (2 per cent) required secondary closure. In fact, this 2 per cent figure for perineal fistula has been constant throughout the entire series totaling more than 800 cases, although this complication has been conspicuously absent since the institution of retention catheter drainage and plastic closure. Fifteen

out of a hundred patients reported urination too frequent, while two complained of difficulty with urination. Nocturia only once or not at all was reported by 61 per cent of these old men, while 89 per cent voluntarily classified themselves as well.

In that a similar questionnaire series, previously reported,⁶ yielded only 82 per cent well, a continued quest for near perfection would seem to be justified. The same applies to all fields of surgical endeavor.

ABSTRACT OF DISCUSSION

DR. OSWALD SWINNEY LOWSLEY, New York: Operative surgery on the prostate is not a thing of the past. I congratulate Dr. Davis on his operation, which for the conservative operation is one of the best. All of these operations are modifications of Dr. Young's original perineal prostatectomy. It encourages every one doing scientific work to do it well, because here is an operation that has lived a very active life for a long time. While Davis and myself and others have made modifications, we cannot get away from the original principles which he laid down. We approach the prostate operation a little differently. We take the entire prostate out, cut the apex of the prostate away from the external membranous urethra and then dissect it free, being careful to preserve the plexus of Santorini. After having removed the prostate we insert ribbon gut into the wall of the urethra and the neck of the bladder in the form of a mattress suture, and when we draw it up we have the entire prostate removed, the neck of the bladder plicated, the urethra plicated and no packing is necessary, nor a bag nor any other hemostatic aid, because we also believe that hemostasis should be performed on the operating table. Sometimes we don't find it necessary to remove the seminal vesicles. We merely cut them across and leave them. The operation should not be done in the case of any man who has not completed his sexual life, because a patient cannot ejaculate after this operation is done. That matter has to be discussed with the patient before the operation is done, because to some patients it seems to be an important matter. This operation has a great number of advantages. The conservative perineal prostatectomy leaves a cavity in which there is a great deal of slough and sometimes these people maintain a constant infection and a puddle of urine the rest of their lives. That is eliminated by the procedure which I have described. We have no incontinence with this operation, owing to the plication of the urethra and the plication of the bladder neck. We have no chance for such patients to develop cancer of the remaining posterior lobe.

DR. HUGH H. YOUNG, Baltimore: The motion picture which Mr. William P. Didusch has made for Dr. Edwin Davis is fine. The exposure of the prostate, after division of the recto-urethralis muscle, demonstrates clearly how simple and safe this procedure is. Done in this way the membranous urethra is avoided, and there is no danger of incontinence or rectal injury. The inverted V capsular incision, the complete enucleation of the prostate in one piece with the assistance of his distensible bag, is beautifully shown. Dr. Davis also uses the bag very effectively in placing the sutures to draw the vesical neck down to cover the space from which the hypertrophied lobes have been removed. The technic which he has employed is similar to that which my associates and I have used very effectively. The situation at the end of the procedure with the operative wound covered by normal mucosa is in marked contrast to the condition left after transurethral resection in very big prostates. In the latter, a great raw area, much of which has been injured by fulguration, is left to heal by granulation. Every man who pretends to do high class surgical urology should master the perineal route, through which alone early cases of carcinoma of the prostate can be cured and tuberculosis of the seminal vesicles and prostate eradicated. There are many other conditions which can be treated alone by perineal surgery. These motion pictures of Dr. Davis and Dr. Belt and others which Mr. Didusch has made should go a long way to arouse interest in perineal surgery, which has been badly neglected by many.

ASPIRATION BRONCHOPNEUMONIA

WITH SPECIAL REFERENCE TO ASPIRATION
OF STOMACH CONTENT

ERNEST E. IRONS, M.D.

AND

CARL WESLEY APFELBACH, M.D.

CHICAGO

The pulmonary diseases most commonly recognized as being associated with the bronchial aspiration of material from the alimentary tract are suppuration and gangrene such as are observed in carcinoma of the esophagus or the aspiration of foreign bodies. A much more frequent pulmonary disease, aspiration bronchopneumonia, the pathogenesis of which seems not to be generally recognized, is also related to the aspiration of material from the alimentary tract, usually material from a dilated stomach. This form of aspiration bronchopneumonia is characterized by hemorrhage, hyperemia, edema and advanced postmortem and retrogressive changes in the lungs.

Bronchopneumonia of the type usually believed to have its origin in the upper respiratory tract is considered to be caused by organisms aspirated from the pharynx or inhaled from the air, which lodge in the smaller bronchi on tissues already damaged by previous disease such as influenza, measles or other infections or colds. The incidence and course of this common type of bronchopneumonia in a community or hospital is thus influenced by the presence of epidemics characterized by pulmonary infections and by the kind of organisms present in the upper respiratory tract of people in the community. In cases of aspiration bronchopneumonia, such a relationship is not demonstrable.

One of the earliest references to aspiration of stomach content as a cause of bronchopneumonia is the report of Ernst Becker¹ in 1887, who described this form of bronchopneumonia in relation to postoperative complications and to gastric diseases. Woillez² in France referred to the same condition, and Balfour and Gray,³ in discussing postoperative complications, called attention to the danger of aspiration of stomach content. Since then there have been repeated suggestions that such postoperative changes might be due to "shock" or again that the aspiration of pneumococci from the pharynx might produce a hemorrhagic type of exudate rather than a fibrinous type by reason of the supposed reduction of resistance of the patient.

The pulmonary complications to be discussed concern acute hyperemia, hemorrhagic and edematous alteration in lung tissue and acute tracheobronchitis. Anatomically these have been variously called "hyperemia and edema of the lungs," "hypostatic bronchopneumonia," "pneumonitis" and "postoperative bronchopneumonia." Clinically the symptoms and physical signs observed in these cases usually pass under the all inclusive diagnosis of bronchopneumonia and are most frequently seen in persons suffering from acute dilatation of the stomach,

From the departments of pathology and medicine, Presbyterian Hospital and Rush Medical College.

Read before the Section on Practice of Medicine at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

paralytic ileus, mechanical bowel obstruction or cerebral and other diseases associated with coma or loss of reflexes. The symptoms, severity of the course and speed of fatal outcome are determined by the amount of stomach content aspirated, by whether free hydrochloric acid is present or whether, in its absence, the aspirated material is rich in bacteria.

In a general hospital of the type of the Presbyterian Hospital of Chicago, the incidence of traumatic cases and contagious diseases is low. The average occurrence of aspiration pneumonia is found to be about 20 per cent of all deaths (necropsies). These figures are based on the postmortem interpretation of the characteristic criteria enumerated (table 1).

For the recognition of bronchopneumonia caused by the aspiration of material from the gastrointestinal tract, it is important that the necropsy be done within an hour or two after death. The bacteriologic examination of fresh tissues and the observation of postmortem alterations are more distinct and reliable than in cases in which several hours has elapsed before the necropsy and in which general postmortem changes throughout the body confuse the interpretation of alterations caused by the aspirated material.

The lungs are overdistended with air and do not collapse when the sternum is removed, owing to the presence of aspirated material and exudate in the bronchial tree and to the presence of hemorrhage and edema of much of the lung tissue.

The lungs are increased in weight in all cases except in those in which death occurs within a few minutes after the aspiration of material sufficient to produce asphyxiation. The increase in weight on the average is at least 200 or 300 Gm. for each lung and often may reach levels of 700 or 800 Gm. The increase in weight is due chiefly to hemorrhage and edema of the alveolar spaces. Intense hyperemia of the alveolar capillaries also contributes to the increase in weight. Usually the color of the blood in the alveolar spaces and alveolar capillaries is altered by the aspirated material, causing the blood in the lung to be much darker than that observed elsewhere in the body and the tissues to be stained by hemolyzed blood. This is important because in instances of pneumonia caused by the usual respiratory organisms hemolysis and postmortem change are not characteristic of the alterations in lung tissue. In cases in which there are no pulmonary complications, the lungs undergo postmortem change slowly, in contrast to the alterations in the abdominal organs. Thus, advanced changes in the lungs indicate that material has been introduced into them that can accelerate postmortem alterations.

When the bronchial tree is examined a prominent characteristic is intense hyperemia, usually of a much greater degree than that observed in pneumonia caused by the pneumococcus. If death has occurred soon after the aspiration, much of the material in the bronchial tree, even in the smaller bronchioles, has the gross characteristics of the material observed in the gastrointestinal tract.

The hemorrhagic and hyperemic regions are unevenly disseminated in the lung tissue in contrast to the evenness of distribution in passive hyperemia and edema which have resulted from cardiac disease. Acute erosions and acute esophagitis are frequent accompaniments even in patients who have not had a tube introduced into the stomach.

Associated complications that suggest the possibility of aspiration of gastrointestinal material are dilatation of the stomach and small bowel, mechanical bowel obstruction, acute generalized peritonitis, particularly if paralytic ileus is present, and diseases of the brain that have produced coma.

Another striking characteristic is disclosed by routine cultures of lung parenchyma, the bronchial tree, the stomach and blood from the right ventricle. In acute aspiration bronchopneumonia, the bacterial flora of the lung, bronchial tree and stomach are almost identical, and ordinarily the cultures of blood from the right side of the heart are sterile. Furthermore, in bronchopneumonia caused by the organisms usually found in respiratory infections, pure cultures of the causative bacterium are characteristic, whereas in cases of acute aspiration bronchopneumonia multiplicity of kinds of organisms is the rule, and the organisms are of the type commonly found in the gastrointestinal tract in the absence of free hydrochloric acid in the lumen of the stomach.

If material from a dilated stomach in which there is no free hydrochloric acid is introduced into the bronchial tree of a dog, the same types of hemorrhagic, hyperemic and edematous alterations in the lung are

produced as are observed in persons in whom the pathologic changes interpreted as aspiration bronchopneumonia are found at necropsy.⁴

The characteristic microscopic changes are intense engorgement of the alveolar capillaries with erythrocytes, edema and hemorrhage into the alveolar spaces. Patients who have survived for at least several hours show some degree of polymorphonuclear leukocytic exudation. Another outstanding characteristic is the extensive desquamation of the lining of the bronchial tree with aspiration of the desquamated cells into the alveolar spaces. In lungs the site of other forms of pneumonia, removed from one to two hours after death and properly fixed, the bronchial mucosa is usually intact, whereas in cases of aspiration bronchopneumonia there is frequently extensive loss of bronchial mucosa. In the submucosa of the bronchial tree there is marked active hyperemia.

The tissues removed from the thorax have lost their capacity for distinct staining in contrast to tissues removed from other portions of the body, indicating a disproportionate degree of postmortem change in the lungs. The erythrocytes in the alveolar spaces, and often those in the capillaries, have lost a large amount of their hemoglobin so that they stain only as shadowy outlines. If a sufficient number of sections are made, particles of undigested food may be identified in the

alveolar spaces near regions of hemorrhage and edema. Often large masses of bacteria are present in the altered regions and, among these, gram-positive bacilli are common.

The organisms most frequently found in the lung tissue, bronchial tree and stomach are colon bacilli,

gram-positive anaerobic bacilli, diphtheroids, staphylococci, yeasts, streptococci and occasionally pneumococci.

The general custom in the performance of necropsies seems to be to omit the routine cultures described. It has generally been assumed that postmortem invasion of the body occurs quickly and that such bacteriologic examinations are not significant in the interpretation of disease processes in the body. It has been our experience that cultures made of tissues within one to two hours after death of persons who have died from non-infectious diseases are almost all sterile with the exception of those of the intestinal tract. If there are no gross alterations in the lung tissue, cultures reveal few or no organisms. In cases of lobar pneumonia, pneumococci are present in abundance, usually in pure culture. It is significant that, in bodies in which the alterations described were found, cultures revealed large numbers of bacteria in the lung tissue and none in the blood stream. This indicates that the organisms were introduced into the lung by way of the bronchial tree.

Postmortem regurgitation of material into the bronchi does not induce active hyperemia. The material is not

found in the bronchioles, and the lung tissues are not altered by hyperemia and edema. Bacteriologic examinations made of fresh tissues will easily demonstrate the relationship between antemortem bronchial aspiration of gastrointestinal material and the changes in the lung tissue.

In patients in whom at necropsy extensive aspiration pneumonia is found, the antemortem diagnosis has sometimes been acute dilatation of the heart, cardio-

vascular collapse, shock, pulmonary embolism, coronary thrombosis, compression atelectasis and bronchopneumonia. Such diagnoses are evidently clinical attempts to account for sudden or unexpected changes in the patient's condition. Frequently this form of pneumonia is only the terminal event in the illness of patients who would shortly die of other diseases, but in a considerable number it is a major complication and determines the fatal outcome. In some instances at least this might have been avoided.

A review of the associated pathologic changes suggests some of the more obvious causes leading to aspiration pneumonia. Of the 169 recognized instances, in forty there was dilatation of the stomach, or obstruction or infarction of the bowel, conditions frequently leading to eructations and vomiting (table 2). Aspiration pneumonia is frequently associated with operations on the stomach and biliary tract (table 3). In another group of thirty-three instances of nonsurgical conditions such as cerebral thrombosis or tumor, uremia, meningitis and coma, which obviously lead to abolition of protective reflexes, aspiration bronchopneumonia was present (table 4).

A study of progress notes and nurses' records of patients in whom aspiration pneumonia was found

showed that hiccup, retching and nausea were more common than vomiting. One patient, with brain tumor, who was continuously and uninterruptedly watched during his postoperative course, had slight diaphragmatic contractions but no vomiting whatever, yet at necropsy extensive and typical aspiration pneumonia was found. It is believed that the postoperative use of continuous aspiration of the stomach has reduced the incidence of this form of pneumonia.

Another group of cases which contributes a rather high incidence of aspiration pneumonia (fifteen) is that of operations on the prostate gland and urinary bladder. Patients in this group are usually advanced in age and often in other respects are poor surgical risks. In such patients ileus is not infrequent.

Pulmonary complications suggestive of pneumonia in patients with evident dilatation of the stomach or other gastrointestinal obstruction, or in patients with diaphragmatic spasms, hiccup or vomiting, are likely to be due to aspiration of stomach content and contribute to the large group of aspiration pneumonia. Hiccup and slight eructations are more common than frank vomiting, possibly because patients able to vomit vigorously are more often in possession of active tracheobronchial reflexes and are better able to expel such foreign material as enters the trachea.

While this discussion is based on necropsies and deals necessarily with the cases of more severe involvement, clinical studies suggest that a considerable number of nonfatal respiratory complications in patients after oper-

ations and in those suffering from other diseases in which there occur eructations and vomiting, or in patients in whom the tracheobronchial reflexes are dulled, are caused by the aspiration of regurgitated stomach content. Undoubtedly, many of these patients recover, possibly because the aspirated material contains hydrochloric acid and consequently few bacteria.

In this connection, the conclusions of King,⁵ who made a careful clinical study of postoperative pulmonary complications combined with painstaking correlations with x-ray films, are of interest:

Purulent bronchitis and pneumonitis are present in practically all instances of the type of pulmonary complication here described. Atelectasis is associated with the infection in about one half the cases, but severe and fatal cases are usually true bronchopneumonias without evidence of atelectasis at any stage.

Complications occur especially in males following operations on the stomach and duodenum, gallbladder and intestines. . . . Seasonal and preoperative respiratory infection play a minor part. . . . From a statistical standpoint, the type of anesthesia is without significance.

SUMMARY

Aspiration of regurgitated stomach content is one of the frequent causes of pulmonary complications in persons who have undergone operations or who are suffering from diseases in which the protective tracheobronchial reflexes are impaired. Aspiration bronchopneumonia causes characteristic alterations in the tissues of the lungs and thorax, recognizable most surely when necropsies are made within an hour or two after death. Cultures of lung tissue, tracheal and stomach contents and blood afford additional evidence. Experimentally, the characteristic manifestations in man can be produced in dogs by the intratracheal injection of stomach content.

Aspiration bronchopneumonia is a relatively frequent finding in persons dead of all causes. In many it is a major cause of death.

In the more severe cases it can be recognized clinically if the conditions under which it most frequently occurs are kept in mind. In less severe cases its occurrence may be surmised.

122 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. J. P. SIMONDS, Chicago: The clinical diagnoses commonly made in this type of pneumonia are stated in the paper. The pathologist usually designates the condition, which he knows has certain specific characteristics, as a terminal bronchopneumonia without inquiring too closely into the pathogenesis of the disease. In calling attention to this subject, the authors have done a real service. The characteristic pathologic changes described in aspiration bronchopneumonia are pulmonary hyperemia, edema and hemorrhage. These conditions in the lungs, with their huge vascular bed and capacity for impounding blood and permitting fluid and red cells to escape from it, can easily produce as a result of chemical or even bacterial injury a clinical condition which answers to the well known characteristics of shock, namely fall in blood pressure and increase in the concentration of the circulating blood. I should like to ask whether there was any difference in the incidence of shock-like symptoms after the aspiration of acid gastric juice on the one hand, or of nonacid gastric juice, rich in bacteria, on the other. A purely chemical irritant, such as strongly acid gastric juice, would induce an inflammatory reaction with its hyperemia, edema and hemorrhage more quickly than would nonacid gastric juice, because the development of the inflammation would have

to wait on the slower bacterial growth. Every pathologist has observed bronchopneumonias at autopsy which differ from the ordinary types in the intense hyperemia of the mucosa, the marked desquamation of the epithelium of the bronchi and bronchioles, the extreme degree of lacking of red blood cells in the exudate within the alveoli or the large masses of bacteria in the exudate when red cells are not so numerous. These types Dr. Irons and Dr. Apfelbach have shown are the result of the action of aspirated gastric contents on the lung. I should like to ask Dr. Irons to what extent examination of the sputum has been used in attempts to make a correct clinical interpretation of this condition. From the pathologic changes in the lungs, one might expect the sputum from these patients to have certain rather distinctive characteristics. As 71 per cent of the patients in whom Dr. Apfelbach found aspiration bronchopneumonia at autopsy were from surgical services of the hospital, I regret that the surgical section cannot also hear this paper, because so many of the cases concern surgical conditions. It is evident from the facts presented that prophylaxis is more important than treatment of aspiration bronchopneumonia. This paper is an excellent example of the value of full cooperation on a basis of equality of clinician and pathologist in a study of problems of this kind.

DR. WILLIAM J. KERR, San Francisco: Dr. Irons and Dr. Apfelbach have made an important contribution. I think all of us have observed the conditions, both clinically and at the autopsy table, but I admit that I have not appreciated fully the nature of this condition. The cultural studies, as the authors have pointed out, are of considerable importance especially if the tissues can be seen soon after death; we all have had observations in the autopsy room where the pathologist would say "It is of no value to make cultural studies in this particular condition," but the authors have shown that it is important if we wish to get to the bottom of the problem. More attention should be given to the use of other measures which will prevent the diaphragm from being fixed by putting on tight binders and that sort of thing, which may be harmful; but everything should be done which will facilitate respiration and normal upper abdominal function. In view of the fact that a number of these arise in connection with shock and semiconsciousness, we should keep in mind that many patients who are in the terminal stage of some chronic and incurable disease may also have this condition, about which we may be able to do but little. The pictures which were shown were very realistic. In fact, I can see more in the picture than I can sometimes see at the autopsy table in examining the specimens.

DR. CARL W. APFELBACH, Chicago: In answer to Dr. Simonds's question about the difference between this condition, when produced by acid containing fluid in contrast to non-acid containing stomach content, I would say this: In experiments, Dr. Christianson and I found that gastric fluid containing normal amounts of hydrochloric acid usually did not produce death, but a temporary hyperemia of the lungs occurred. Also stomach content free of hydrochloric acid and containing bacteria, when passed through a Berkefeld filter, also produced only a transitory hyperemia of the lungs. Death occurred in animals only if stomach content containing bacteria was used. I do not know that I can recognize the alterations in human lungs produced by the aspiration of stomach content that has a normal constituency of acid. As far as the examination of sputum during life is concerned, we have had only a few cases available. This is due probably to the fact that cardiovascular collapse or heart failure is diagnosed clinically, and sputum consequently is not sent to the laboratory. Furthermore, because of the weakened condition of these patients, sputum is infrequently obtained. I believe that the outstanding anatomic changes to be observed are the following: The necropsy should be performed soon after death so that postmortem changes do not hide and confuse the alterations of acute aspiration of stomach content. Routine cultures of lungs, blood material from the gastrointestinal tract, and all exudates from each postmortem examination allow a better evaluation of the bacterial flora found in aspiration bronchopneumonia. We have observed that postmortem invasion of the body by bacteria does not occur as rapidly as is generally believed, except in gas bacillus infections.

TREATMENT OF PSORIASIS

JOHN F. MADDEN, M.D.

ST. PAUL

In this communication I am reporting the results of my continued observations on the treatment and handling of patients with psoriasis. To be sure, no specific remedy has been discovered but some of the facts gleaned are worth recording.

One hundred and twelve patients were treated from October 1937 to October 1939 with vitamin D, vitamin B₁, vitamin B complex, brewers' yeast, vitamin C, liver extract, diluted hydrochloric acid, estrogenic substance, sulfanilamide, bismuth salicylate, anterior pituitary extract or adrenal cortex extract alone or in combination with one another or in combination with a low fat diet. All the patients were ambulatory, some received several types of treatment, and only those with definite clinical and microscopic psoriasis were studied. The patients were started on the type of treatment being used when they were first examined. If a change was not noted in the psoriasis after a certain time had elapsed, another kind of treatment was given. Patients were treated at least four weeks unless they could not tolerate the medication. Local applications were not used. The following types of treatment were chosen because of favorable reports in the literature regarding their use in psoriasis or because of the general empiric use of some of the medications in many cutaneous diseases:

VITAMIN D

Vitamin D has received considerable attention as a treatment for psoriasis. Monash¹ treated six patients with from 12 to 20 drops of viosterol and noted improvement in all the cases. Krafka² observed that three cases of psoriasis were greatly benefited by the administration of vitamin D given in the small dose of 6 minims (0.36 cc.) of halibut liver oil with viosterol. Cedar and Zon³ treated a series of fifteen patients from 30 to 50 years of age who had chronic widespread psoriasis with from 300,000 to 400,000 units of vitamin D in the form of viosterol. In eleven of the fifteen cases the psoriasis completely involuted within six to twelve weeks. One of their cases had two recurrences in which equally good results were obtained with vitamin D. Brunsting⁴ observed marked clinical improvement in over 60 per cent of his nineteen cases treated with massive doses of vitamin D.

Twenty-four adult patients were given from 350,000 to 450,000 units of vitamin D daily on bread in the form of irradiated ergosterol for a period of four to twelve weeks. The eruption showed no change in eighteen cases, improvement in four cases, and it became steadily worse in one case and entirely disappeared in one case. The medication was stopped in eight cases because of reactions such as nausea, loss of appetite, vomiting, diarrhea and abdominal pain accompanied by

loss of from 6 to 11 pounds (2.7 to 5 Kg.) of body weight. All of these reactions were generally present in each patient. The improvement of psoriasis usually accompanied or followed the reactions. The patient whose eruption entirely involuted had one of the most severe reactions. One patient who could not return to the hospital for two weeks but continued to take the medication developed severe diarrhea, nausea, vomiting and inability to retain food and lost 11 pounds (5 Kg.) of body weight. It was necessary to confine him to the hospital for two weeks and administer intravenous feeding. In this group of psoriatic patients vitamin D was not only generally of no value but a dangerous medication in some cases. It should never be given in massive doses except when the patient is under frequent observation. The patients who tolerated vitamin D well usually showed no change in their eruption. The degree of improvement in the psoriasis corresponded to the severity of the reaction to vitamin D. When the reactions subsided the psoriasis recurred.

VITAMIN B₁

Twenty-seven patients received from 750 to 1,250 international units of vitamin B₁ daily by mouth for a period of from four to ten weeks. The psoriasis showed no change in eighteen cases, marked improvement in five cases and complete involution in four cases. The four patients remained free from eruption from three months to two years. When psoriasis recurred the same treatment had no effect in two cases but did effectively control the eruption in the other two cases.

VITAMIN B COMPLEX

Fourteen patients were given vitamin B complex containing from 600 to 900 international units of vitamin B₁, from 80 to 120 Sherman units of vitamin B₂ and an unstated quantity of vitamin B₆, B₁₂, B_c and nicotinic acid for a period of from four to ten weeks. Psoriasis showed no change in thirteen cases and became much worse in one case.

BREWERS' YEAST

Twenty patients were given 54 grains (3.4 Gm.) of brewers' yeast containing 85 international units of vitamin B₁ and 143 Sherman units of vitamin G (B₂) each day by mouth for a period of from four to eight weeks. The psoriasis did not change in fourteen cases, became worse in four cases and showed marked improvement in two cases.

VITAMIN C

Reiss⁵ observed no clinical improvement in psoriasis treated with vitamin C, although there was a definite decreased excretion of vitamin C in all his cases. Volpe⁶ stated that his cases responded in a "striking" manner to the administration of ascorbic acid. Spillman, Drouet and Weille⁷ found that anterior pituitary and vitamin C had little effect on a single case of psoriasis.

Seventeen patients were given from 100 to 150 mg. of ascorbic acid daily by mouth for a period of from four to ten weeks. The psoriasis showed no change in thirteen cases, became worse in three cases and improved in one case.

LIVER EXTRACT AND DILUTED HYDROCHLORIC ACID

Gruenberg⁸ found that liver therapy decreased the tendency toward recurrence in psoriasis and favorably influenced healing of existing lesions. Spiethoff⁹ also thought that liver extract was effective in the treatment of psoriasis and helped prevent or delay recurrences but that it was of value only as long as the liver was given. In an analysis of the gastric contents of thirty-five patients with psoriasis Madden¹⁰ noted that free hydrochloric acid was entirely absent or below normal limits in 61 per cent and that total acid was absent or below normal in 64 per cent of his cases.

Thirty-five patients were given liver extract equivalent to approximately 180 Gm. of fresh liver and 75 drops of diluted hydrochloric acid daily by mouth for a period of from four to eight weeks. The psoriasis showed no change in twenty-one cases, became worse in four cases, improved in six cases, involuted except for a few papules in one case and entirely disappeared in three cases. Lesions recurred in one month in one case and were not influenced by a resumption of treatment. The other two patients have remained free from psoriasis for thirteen months. The patients whose psoriasis disappeared showed diminished or absent free and total hydrochloric acid in their gastric contents.

ESTROGENIC SUBSTANCE

Keller¹¹ gave female sex hormone in the form of 150 mouse units of progynon daily for twenty-five days to a patient with psoriasis arthropathica and amenorrhea with favorable results. Sochatzy¹² treated one case with corpus luteum extract by mouth and the psoriasis healed in twenty days. Sperry¹³ treated one patient who had amenorrhea and psoriasis with 3 cc. of theelin daily intramuscularly until 15 cc. had been given. The patient menstruated and the eruption began to disappear. She missed a menstrual period and the lesions recurred. The psoriasis again disappeared following the use of more theelin.

Twenty-three patients were given estrogenic substance for a period of from four to eight weeks. Eleven patients received 4,000 international units of estrogenic substance daily by mouth. The eruption showed no change in nine cases and involuted except for a few scattered papules in two cases. One of these patients was 64 and the other 32 years old. Twelve patients received from 1,000 to 10,000 international units of estrogenic substance intramuscularly twice a week. The psoriasis remained the same in eight cases, became much worse in two cases and showed noticeable improvement in two cases.

SULFANILAMIDE

Sulfanilamide was given in 10 grain (0.65 Gm.) doses three times daily to ten patients for a period of from two to four weeks. The drug was stopped in six cases because of vertigo, nausea, cyanosis or dermatitis. The state of the psoriasis did not change in any case.

BISMUTH SALICYLATE IN OIL

Eight patients were given 1 cc. of bismuth salicylate in oil containing 2 grains (0.13 Gm.) of bismuth salicylate at weekly intervals for five weeks. The psoriasis showed no change in seven cases and entirely involuted, except for two small papules on the glans penis, in one case in which there was a generalized guttate eruption. The eruption began to disappear after the first injection in this case and has not recurred during thirteen months of observation.

ANTERIOR PITUITARY EXTRACT

Walinski¹⁴ gave anterior pituitary extract in six cases of psoriasis and five cases improved but none were completely cured.

Six patients were given anterior pituitary extract equivalent to 30 grains (2 Gm.) of fresh anterior pituitary lobe substance daily by mouth for a period of four weeks. The psoriasis did not change in five cases and improved in one case.

ADRENAL CORTEX EXTRACT

Riehl¹⁵ treated twenty patients with adrenal cortex extract and found the clinical effect uncertain and the results disappointing in most cases and acute exacerbations appeared during treatment in some cases. Gruenberg¹⁶ treated 150 psoriatic patients with adrenal cortex extract with good and in some cases excellent results. He gave from 2 to 6 cc. daily in increasing doses. He thought a low fat diet added to the success of adrenal cortex therapy. Richter¹⁷ thought that every one of his sixty-five cases showed disturbed internal secretion, principally a disturbance of the adrenal cortex, and that the hypophyseal hormone was not indicated in treatment because it increased psoriasis. Gruenberg¹⁸ stated that psoriatic patients showed an increased sulfur content of the skin, and since the adrenals, especially the cortex, influenced the sulfur content of the skin he treated twelve patients with adrenal cortex extract. He injected from 2 to 3 cc. of the adrenal cortex extract intramuscularly each day and two cases almost healed. Kissmeyer, Chrom and Jacobsen¹⁹ treated twenty-eight cases of psoriasis with cortical extract of pig's adrenals and "permanently cured" nine patients, seven showed improvement and twelve were not improved.

Six patients were given 1 cc. of adrenal cortex extract representing 40 Gm. of fresh adrenal cortex intramuscularly twice a week for a period of from four to eight weeks. The psoriasis remained stationary in five cases and improved steadily in one case.

LOW FAT DIET AND VITAMIN B₁

Thirteen patients were given a low fat diet and 1,000 international units of vitamin B₁ daily by mouth for a period of from four to ten weeks. The low fat diet was not a measured or weighed diet but merely one in which the foods high in fat content were eliminated. The psoriasis remained the same in three cases, improved in three cases, involuted except for a few

scattered papules in four cases and entirely disappeared in three cases. The eruption reappeared in six months in one case, in eight months in one case, and has not reappeared after one year's observation in the third case. The treatment effectively controlled the recurrences in the two cases.

LOW FAT DIET AND LIVER EXTRACT

Seventeen patients were given a low fat diet and liver extract equivalent to approximately 180 Gm. of fresh liver daily by mouth for a period of from four to eight weeks. The psoriasis showed no change in seven cases, became worse in two cases, improved in seven cases and entirely involuted in one case. This patient has been free from psoriasis for seven months.

LOW FAT DIET, VITAMIN B₁ AND ANTERIOR PITUITARY EXTRACT

Nineteen patients were given a low fat diet, 750 international units of vitamin B₁ and anterior pituitary extract equivalent to 30 grains (2 Gm.) of fresh anterior pituitary lobe substance daily by mouth for a period of from four to eight weeks. The psoriasis showed no change in sixteen cases, improved in two cases and almost disappeared in one case.

LOW FAT DIET, VITAMIN B₁, ANTERIOR PITUITARY EXTRACT AND ADRENAL CORTEX EXTRACT

Pulay²⁰ concluded that there are three factors to be considered in the treatment of psoriasis: treatment by diet, endocrine therapy and vitamin B therapy. His patients were given anterior pituitary extract, pancreatic extract, adrenal cortex extract, vitamin B₁ and a diet in which fats and proteins were eliminated as far as possible. In 850 cases 75 per cent were healed. The results were durable only if the patients adhered to the diet and took the hormones from time to time.

Twenty patients were given a low fat diet, 750 international units of vitamin B₁ daily by mouth, 1 cc. of adrenal cortex extract representing 40 Gm. of fresh adrenal cortex intramuscularly twice a week, and anterior pituitary extract equivalent to 30 grains (2 Gm.) of fresh anterior pituitary lobe substance daily by mouth for a period of from four to eight weeks. The psoriasis showed no change in thirteen cases, improved in six cases and entirely involuted in one case. This patient remained free from psoriasis for two months and a resumption of treatment did not control the eruption when it recurred.

COMMENT

Vitamin D was not only generally of no value in this group of cases of psoriasis but was a dangerous medication in some cases. It should never be given in massive doses except when the patient is under frequent observation. The patients who tolerated vitamin D well usually showed no change in their eruption. The degree of improvement in the psoriasis corresponded to the severity of the reaction to vitamin D. When reactions subsided the psoriasis recurred.

Psoriasis improved greatly in five and completely involuted in four out of a group of twenty-seven cases following the administration of vitamin B₁. When psoriasis recurred the same treatment had no effect in two cases but did effectively control the eruption in the other two cases. Vitamin B₁ is of some value when given alone and it effectively controlled 50 per cent of the recurrences.

Psoriasis improved in six, involuted except for a few papules in one and entirely disappeared in two of a group of thirty-five cases in which liver extract and diluted hydrochloric acid were given. Recurrent lesions in one case were not influenced by a resumption of treatment. The patients whose psoriasis disappeared showed diminished or absent free and total hydrochloric acid in their gastric contents.

Estrogenic substance was of benefit in four of a group of twenty-three cases. Psoriasis in two patients 32 and 64 years of age involuted except for a few scattered papules, and two patients became much worse while receiving the same treatment.

Bismuth salicylate in oil caused involution, except for two small papules on the glans penis, in one patient with a generalized guttate eruption of a group of eight patients with psoriasis.

Estrogenic substance and bismuth salicylate in oil are of value in an occasional case.

A low fat diet combined with vitamin B₁, liver extract, anterior pituitary extract or adrenal cortex extract was more effective than the foregoing medications given alone. However, the combinations were not as beneficial as a low fat diet given alone in a previously reported series of cases²¹ except when the diet was combined with vitamin B₁. This could be explained by the fact that the patients in this study were ambulatory and their diet could not be positively controlled, while the patients previously treated by a low fat diet alone were hospitalized for varying periods and their diet was positively controlled.

Vitamin B complex, brewers' yeast, vitamin C, sulfanilamide, anterior pituitary extract and adrenal cortex extract were of little or no value in this series of cases.

Considering over 300 psoriatic patients whom I have treated during the the past five years, I believe that it is better to treat the disease than to tell the patient that nothing can be done.

After a considerable experience with the methods outlined, my treatment of choice at the present time is a low fat diet plus 1,000 international units of vitamin B₁ daily by mouth combined with an exfoliating ointment. I well realize that some patients will not respond to this regimen.

350 St. Peter Street.

ABSTRACT OF DISCUSSION

DR. DONALD M. PILLSBURY, Philadelphia: Dr. Madden reported the results of various types of treatment in 112 cases of psoriasis treated in consecutive groups. Each type of treatment was carried out on a group of patients at the same time of year. The various remedies used included, first, vitamin D in a dosage of from 300,000 to 400,000 units by mouth in twenty-four cases, vitamin B₁ by mouth in a dosage of from 75 to 125 international units in twenty-seven cases, vitamin B complex, yeast, combined treatment with liver extract by mouth and diluted hydrochloric acid in a dose of 75 drops daily, estrogenic substance, sulfanilamide in a dose of 30 grains (2 Gm.) daily, bismuth salicylate injections, anterior pituitary extract, adrenal cortex extract, a low fat diet combined with vitamin B₁ by mouth, and liver extract. He found that a low fat diet combined with vitamin B₁ by mouth seemed to produce the greatest degree of improvement. This study resulted in an adequate trial of popular remedies; that is, the vitamin and endocrine preparations. Dr. Madden did not intimate that any startling results as to the cure of psoriasis had been obtained. There is the hope that some light may be thrown on the basic change in psoriasis. There are a variety of remedies which produce

20. Pulay, E.: Le "psoriasis vulgaris" et son traitement, Bull. Soc. franç. de Dermat. et Syph. 42: 1508-1521 (July) 1936.

temporary involution at times. We have no notion of the basic change which has occurred in the patient. The Kefner phenomenon shows that the skin at certain phases of the disease reacts with a characteristic pattern and that with application of an appropriate stimulus a lesion of psoriasis develops in from seven to ten days. The clinical course of psoriasis thus is somewhat better understood; that is, many stimuli seem to cause a flare-up; trauma produces lesions at certain sites, and the localization of psoriatic lesions to the elbows and knees and possibly to the lower part of the back may to some extent be attributed to this. One can't follow the theory all the way through, but it seems to shed some light. The x-rays, light and scratches occasionally produce flare-ups. A consideration of this phenomenon is worth while in the particular type of local treatment at least which is to be used. In an advancing psoriasis it might not be well to use a method of scrubbing the lesions thoroughly because one may be producing a Kefner phenomenon at the site. Treatment of the underlying condition, whether seborrhea or ichthyosis or a monilian infection, is worth while in lessening the amount of irritation which is already present. I should like to ask Dr. Madden if he knows of any control series of these patients. As to vitamin D, his results are in accord with my experience, at least as far as the fact that it has not helped. With regard to vitamin B₁, I think that it might be worth while to give it intravenously in some cases.

DR. JOSEPH V. KLAUDER, Philadelphia: I believe that basic changes in the pathogenesis of psoriasis concern the oxidation-reduction mechanism of the epithelial cell, a view championed by von Kerkhoff (Beiträge zur Kenntnis der Psoriasis vulgaris und ihrer Behandlung, Leipzig, S. Hirzel, 1929). Sulfur compounds, especially glutathione, are essentially physiologic tissue constituents concerned in biologic oxidation-reduction phenomena. There is reported evidence of disturbance of sulfur metabolism in psoriasis. Brown and I reviewed this evidence in our paper on certain phases of sulfur metabolism of the skin in the *Archives of Dermatology and Syphilology* in 1936, in which we reported an abnormally high percentage of sulfur in the skin of patients with psoriasis. I may suggest that, if Dr. Madden continues investigation of the therapeutics of psoriasis, he give consideration to disturbance of sulfur metabolism in order to obtain a clue in treatment of the disease. As pointed out in our paper, extract of the adrenal gland has been used in treatment of psoriasis since it has been shown that such administration increased the sulfur content of the skin of rats and rabbits. Likewise liver therapy, since it has been shown that administration of liver extract causes an increase of glutathione in the skin.

DR. JOHN F. MADDEN, St. Paul: In answer to Dr. Pillsbury's question, I do not know of a control series wherein patients who have not had any treatment over a long period of time have been under medical observation. However, I secured a detailed history in each case and many of this psoriatic group did not have any treatment for a period of years and they gave intelligent observations regarding the progress of the psoriasis. I considered this a control in itself.

Pellagra in Relation to Mental Disease.—The importance of pellagra in its relation to mental disease is increasingly recognized. Pellagra was described in the eighteenth century as occurring in Spain and in Italy, and in the nineteenth century cases were recognized in France, Rumania, Egypt, the United States and the British Isles. In 1866 Howden and Montrose described the first case in the British Isles, but no further mention is made in British literature until in 1909 Brown and Cranston Low described a second case. Since that time numerous cases have been described by other observers. An idea of the prevalence of the disease may be gained from the fact that Lavinder in 1912 estimated that 30,000 cases of pellagra had occurred in the United States of America during the five preceding years; in Italy a yearly estimate of from 50,000 to 60,000 cases is conservative; while in Rumania, with a population of a little over 5,000,000 individuals, there are 40,000 to 50,000 pellagrins. Since from 4 to 10 per cent of all pellagrins show mental symptoms, its psychiatric importance is considerable.—Henderson, D. K., and Gillespie, R. D.: *A Text-Book of Psychiatry for Students and Practitioners*, London, Oxford University Press, 1940.

BIRTH CONTROL CENTERS

REPORT OF 202 IN THE UNITED STATES
FOR THE YEAR 1939

ROBERT L. DICKINSON, M.D.

AND

WOODBIDGE E. MORRIS, M.D.

Vice President and General Medical Director, Respectively,
Birth Control Federation of America

NEW YORK

The maternal health center for contraceptive advice is a comparatively new development in this country. The first of these centers, the Birth Control Clinical Research Bureau, was organized in New York by Margaret Sanger in 1923 with a physician in charge. The fact that 1,208 patients were advised during the first year of the bureau is evidence that it filled a need, for, under the law, its services could not be advertised, nor was it listed among the city's various health agencies.

At the close of 1939, sixteen years after the establishment of the first center, 549 of them were functioning under medical direction in forty-two states. Of these, 171 were located in public health departments, ninety-two in hospital quarters and 286 in settlement houses, church houses and extramural quarters. The majority of the public health services were in North and South Carolina, with seventy and forty-five services respec-

tively. In both these states the state board of health, each county health department and each county medical society were cooperating in this public health service for the underprivileged.

STANDARDS

The growth of centers necessitated supervision and standardization. For a center to be certified by the Birth Control Federation of America, it must conform to the following:

1. It shall be a nonprofit organization.
2. It shall in no way be affiliated with or subsidized by any commercial manufacturer of contraceptives. No member of the sponsoring group or clinic personnel shall derive any profit directly or indirectly from the manufacture, distribution or sale of contraceptives either chemical or mechanical.
3. It shall be staffed by physicians graduated from recognized medical schools and licensed to practice medicine and surgery in their respective states.
4. There shall be a nurse and/or a social service worker in attendance. Where there is a male clinician, a nurse is essential.
5. Adequate clinical and follow-up records shall be kept for each patient. All certified centers are required to submit reports based on these records. (Case record cards and report forms for clinic statistics are furnished by the federation.)
6. The center shall have a representative medical advisory board (a minimum of three physicians exclu-

sive of the clinicians) which shall decide all matters of medical policy in reference to the center.

Other standards which are recommended to local centers are that fees should parallel those in private or public clinics in the community, that patients found in need of surgical or other medical care are to be referred to private physicians or clinics, that the methods of

or individuals whose income level was above the limit set by the medical and lay boards of the centers. Where patients were ineligible because of high income for service at the centers, referral was made to private physicians in the community.

SOURCE OF REFERRAL

For the period from Jan. 1, 1939, to Dec. 31, 1939, a total of 46,582 new patients was accepted for contraceptive advice. The sources of referral are given in table 1. The major source of referral—other patients—accounts for some 48 per cent of new cases, while 39 per cent came from physicians and social agencies. By 3,687 women (8 per cent) the clinic had been heard of from friends or they had read about the service and had come unreferred.

REPRODUCTIVE HISTORY

The total number of preclinic pregnancies reported by these new patients was 122,775, or an average pregnancy rate of 2.64. As the report forms did not specifically ask for the number of stillbirths, data on these have not been included in the reported pregnancies.

The average parity, prior to coming to the center, was 2.27, showing an average pregnancy wastage of 0.37. The percentage of pregnancy wastage (13.8) is considerably lower than the 28.5 per cent (due to spontaneous and induced abortions) reported by Marie Kopp in her study of cases at the Birth Control Clinical Research Bureau in New York City during the period from 1925 to 1929.¹ A comparison with the average pregnancy rate reported by Kopp (3.89) shows a decrease of 1.65. This decrease may indicate that the women applying for contraceptive advice today generally come at an earlier period in their reproductive cycle or that the methods used prior to clinic visit are more effective than those used a decade ago.

METHODS PRESCRIBED

The methods prescribed for this group of women are given in table 3. The prescription of an individually fitted rubber diaphragm and spermicidal jelly was found suitable for more than 90 per cent of the women who received advice. A small group of women (2.3 per cent) examined were advised on the use of the cervical cap and jelly or cream because of cystocele, rectocele, marked prolapse and other conditions. The prescription of a rubber sponge with foam-producing spermicidal powder was given in 2.0 per cent of the cases reported

contraception and supplies to be used at the center are to be determined by the local medical advisory board, and that when clinical research is contemplated the medical committee of the federation be notified in order to avoid unnecessary duplication and to assure all safeguards.

All state leagues which are affiliated with the federation are expected to have medical advisory boards whose function it is to advise with local centers and their medical boards on procedure and requirements for admission of patients.

INTRODUCTION

With the rapid growth of birth control service in the United States, not only in the extramural centers but more recently in hospitals and public health services, an annual analysis of the data assembled by these services is in order.

Reports have been gathered by the Birth Control Federation of America from 202 birth control centers in thirty-three states and the District of Columbia. Included in the reports are those of twenty-three clinics in hospital quarters and eleven health department services.

Eligibility requirements in all but a few of these centers restrict contraceptive service to the indigent; in more than half there are required as well medical indications such as chronic kidney disease, cardiovascular disease, tuberculosis, venereal disease, nervous and mental disorders, pelvic deformities, adnexal disease, spacing of children, and so on. In general, the list of indications includes multiparity, particularly when the income level is low and when distinct evidence of undernourishment is at hand. Cases are accepted on medical indications satisfactory to the clinician in charge and his advisory board.

NEW PATIENTS

The total number of new applicants for birth control advice at the centers during 1939 was 48,214. Of this number 1,632 were not accepted as patients for various reasons, such as existing pregnancy, unmarried women, married women who are not living with the husband,

on, when other methods were found unsuitable or unacceptable. Another method prescribed as an alternative to the diaphragm and jelly method was the use of a condom and jelly for 1.6 per cent of the women advised.

REFERRAL FOR OTHER CARE

During the course of all physical examinations at the centers, 6,582 (6 per cent) of the women examined were reported to be in need of other medical or surgical care and were referred either to other clinics or to their own physicians for the necessary care. The detection of pathologic conditions that otherwise might have been left undiscovered was thus made possible through examination at the birth control center.

SOCIO-ECONOMIC DATA

Information was obtained regarding the 46,582 new patients' economic status as shown in table 4. It will be noted that approximately 34 per cent of the new patients advised were either on relief or unemployed. That the majority of the employed group was in the low income brackets is evident from the fact that 28,221 (60.5 per cent) of the new patients were advised and given materials either without any charge or for a fee of \$1 or less.

RELIGION

Data gathered concerning the religious affiliations of new patients were sent by the majority of centers, although a few do not include the question of religion in their case histories. The figures reported are given in table 5.

COLOR

White patients (86.7 per cent) were in the majority, Negro patients accounting for only 11.9 per cent of the total. (The United States Negro population is 9 per cent, according to the estimate of the National Resources Planning Board.) In addition, 1.4 per cent other patients—the majority Mexican Indians—were admitted to the centers in the past year.

OLD PATIENTS

In addition to the 46,582 new patients admitted and advised, 69,170 old patients made return visits for examination and necessary contraceptive supplies. In most of the reporting centers, patients are requested to return for check-up examinations at stated periods, varying with the local clinic's procedure. The check-up consists of a vaginal examination by the clinic physician and a check on the fit of the diaphragm or cap and of the patient's technic. At the time of these check-ups the physician also examines the condition of the diaphragm or cap. During 1939, old patients made 85,591 visits for examination. In this group of 69,170 old patients, 1,130 women reported that since their physical and economic condition had improved they were now planning to have babies.

CONCLUSION

A total of 115,752 patients (46,582 new and 69,170 old) was advised in the 202 centers reporting to the Birth Control Federation of America during 1939. Medical direction is universal and a medical advisory board general. These are nonprofit organizations with no commercial affiliation. They keep records. Patients are accepted only on adequate indications. Sixty per cent of the service is given without charge or for the cost of materials, that is, to people who would probably not go to private physicians. More than one third were on relief or unemployed.

COLD VACCINES

A FURTHER EVALUATION

H. S. DIEHL, M.D.; A. B. BAKER, M.D.

AND

D. W. COWAN, M.D.

MINNEAPOLIS

Something over a year ago we reported a series of controlled studies of several vaccines which are advocated for the prevention of colds. One of these was a mixed bacterial vaccine for subcutaneous administration, the organisms in which were destroyed mechanically instead of by heat. The other two vaccines were of the type recently developed for oral administration. The results of these studies were summarized as follows:¹

In a carefully controlled study of the value of three different vaccines which are recommended for the prevention of colds the subjects were cold-susceptible students of the University of Minnesota.

A "control group" was observed during each year of the study. Such groups were chosen at random from the students who applied for cold prevention treatment; the members were treated in exactly the same manner as those of the vaccinated groups, and they believed throughout the period of the experi-

* Reported from memory.

ment that they were receiving vaccine. Sterile physiologic solution of sodium chloride was administered hypodermically as a control for the subcutaneously administered vaccine and lactose filled capsules as a control for the vaccines administered orally.

One of the most significant aspects of this study is the great reduction in the number of colds which the members of the control groups reported during the experimental period as compared to the number that the same students reported for the previous year. In fact, these results were as good as many of those reported in uncontrolled studies which recommend the use of cold vaccines.

The group which received vaccine subcutaneously experienced an average of 25 per cent less colds per person than did the control group. This difference occurred during both years of the study and is statistically significant. Practically, however, it is of little or no importance, because a reduction of 25 per cent in the average number of colds in a group of individuals is not sufficiently great to justify the time and expense involved in carrying out the intensive vaccination procedure which was utilized.

The group which received the polyvalent vaccine administered orally experienced just as many colds as the control group during both years of the study.

1. Diehl, H. S.; Baker, A. B., and Cowan, D. W.: Cold Vaccines: An Evaluation Based on a Controlled Study, *J. A. M. A.* 111: 1168-1173 (Sept. 24) 1938.

The results reported by the students who took Rosenow's streptococcus vaccine parallel exactly those reported for the control group.

Although the data are not entirely conclusive, there is no evidence in this study either that vaccines reduce the complications of colds or that the condition of the nose and throat is related to the frequency of colds in a cold-susceptible group.

THE SUBSEQUENT STUDY

Following the publication of the foregoing report, we received several communications from physicians who felt that we should have included in our studies the traditional type of heat-killed bacterial vaccine, long used for the prevention of colds. It had been our opinion that the results obtained with the mechanically killed bacterial vaccine should be applicable also to the heat-killed vaccine, but since we had no real evidence in this regard we felt that we should continue these studies in order actually to determine results with this type of vaccine.

The conditions of the continuation study were exactly the same as those which were described in our previous report. Comparable experimental and control groups were set up. The experimental groups received the vaccine and the control groups sterile physiologic solution of sodium chloride during the school year 1938-1939. The vaccine² used consisted of the following heat-killed organisms per cubic centimeter: *Staphylococcus aureus* and *Staphylococcus albus*, of each 1 billion; streptococcus, pneumococcus, *Micrococcus catarrhalis*, Friedländer's bacillus and influenza bacillus, of each 400 million. This vaccine was administered subcutaneously as follows:

1. The first dose was 0.1 cc.; for students who had no reactions of consequence to the vaccine the second to the fifth doses inclusive were increased 0.1 cc. each at weekly intervals; the sixth and seventh doses were increased 0.25 cc. each at two week intervals, and thereafter 1 cc. was continued every two weeks throughout the season.

2. For students who had moderately severe local reactions to the vaccine, the dosage was not increased beyond that which produced the reaction, but this particular dosage was continued at two week intervals throughout the season.

3. For students who had severe local reactions or moderately severe general reactions to the vaccine, the dosage was decreased to the largest dose which did not produce a reaction, and this was continued throughout the season.

The control group, the members of which believed that they were receiving vaccine, were given hypodermic injections of sterile physiologic solution of sodium chloride at the same intervals that the experimental groups received the vaccine.

RESULTS

The accompanying table presents a summary of the results reported by students who participated in this study. Ninety-two students, 77.3 per cent, of the experimental group and eighty-eight students, 83 per cent, of the control group continued to the end of the experimental period. There was a greater loss of subjects in the experimental group than in the control group and, according to their own statements, this was due primarily to the reactions from the vaccine.

The uniformity in the average number of colds which the students in these two groups reported having had during the previous year would indicate that the

groups were well equated so far as susceptibility to colds is concerned.

During the year of the study the persons who received the vaccine reported an average of 2.1 colds per person. This is a reduction of 55 per cent from the average of 4.7 colds which these same students reported that they had had during the year prior to the study. This is as great a reduction as has been reported in most of the studies which conclude that these vaccines are of value. However, our control group, who received only physiologic solution of sodium chloride, reported an average of only 1.9 colds during the year of the study, a reduction of 61 per cent from the average of 4.9 colds which was reported for the previous year. From these figures it is apparent that there is no evidence in this study that the vaccine had any influence on the average number of colds suffered per person.

Of the other data shown in this table, the only difference between the groups which seems to be of significance is in the percentage of persons reporting reactions to the vaccination. This shows a very real difference between the two groups. Many of the students who received the vaccine reported quite severe reactions.

CONCLUSIONS

A carefully controlled study of the traditional heat-killed bacterial vaccine for the common cold reveals no evidence that it is of value in a group of cold-susceptible students at the University of Minnesota.

THE DIAGNOSIS OF ECHINOCOCCUS (HYDATID) DISEASE

BY IMMUNOLOGIC REACTIONS WITH SUBSTITUTE
TAENIA ANTIGENS

HARRY M. ROSE, M.D.

AND

JAMES T. CULBERTSON, PH.D.

NEW YORK

Echinococcus disease has never been common in the United States, and the case incidence has decreased considerably since the restriction of immigration in 1924. Nevertheless, this relatively rare disorder continues to be seen with sufficient frequency to warrant consideration, particularly since diagnosis by the usual clinical and laboratory procedures is almost always difficult and uncertain.

The diagnosis of echinococcus disease may be greatly facilitated by employing immunologic procedures such as the cutaneous test described by Casoni¹ or the complement fixation reaction of Ghedini² and Weinberg.³ Neither of these important diagnostic aids has, however, been used to any great extent in this country for the reason that hydatid fluid, which is used as the antigen, is generally unavailable.

In the present report some of the salient features of echinococcus disease are reviewed, and readily available antigens are described which may be substituted for hydatid fluid in performing the Casoni or Ghedini-Weinberg tests.

LIFE CYCLE OF THE PARASITE⁴

Hydatid disease is caused by infestation with the larval stage of a cestode, *Echinococcus granulosus*.⁵ The definitive hosts of this parasite are dogs, wolves and jackals. The adult tapeworms inhabit the intestine of these carnivora, and eggs shed from the gravid proglottids are passed in the feces. Water or vegetation contaminated with infested fecal material may then be ingested by herbivora, usually sheep or cattle, in whose alimentary canals the eggs hatch and deliver hexacanth embryos. These larvae penetrate the intestinal wall and enter the portal circulation, whence they are carried to the liver. Most of the larvae are arrested by the hepatic filter, but not infrequently a few pass through and lodge within the lungs. More rarely still the parasites reach the general circulation and are carried into the brain, bones, kidney, spleen and other organs.

In the tissues where larvae remain viable the characteristic hydatid cysts slowly develop. These cysts are composed of a cuticle of host tissue and an inner germinative membrane from which embryonal tapeworms (scolices) develop in large numbers. Daughter cysts may form by budding from this membrane. Normal cysts are filled with limpid hydatid fluid.

To perpetuate the life cycle of the parasite, the definitive hosts must become infested with the adult worms by ingesting cysts which contain viable scolices. Opportunities for such infestation occur frequently in foreign regions where sheep and cattle are raised in large numbers, and where the offal of slaughtered animals is fed indiscriminately to dogs. The scolices, when swallowed by the dog, evaginate and attach themselves to the intestinal wall by means of their hooklets. Here they again develop into adult, gravid forms.

Hydatid infestation in man, just as in the herbivorous animal, results from the ingestion of eggs passed in the feces of a definitive host. The distribution and evolution of cysts within the human body are similar in all respects. The only considerable difference between hydatid disease in man, as compared with other animals, is that the cysts usually attain a larger size in the human host.

INCIDENCE AND DISTRIBUTION

The incidence of hyatid disease in the United States has never been accurately determined, but Magath⁶ states that less than 500 cases of the disease were reported in the medical literature of North America between 1880 and 1936. When patients suffering from echinococcus disease are seen in this country, they are almost invariably found to be immigrants from world areas where the disease is endemic. The majority of the patients are natives of Italy, Greece, Germany, Russia, Poland or Turkey, and echinococcus disease is most common in those sections of the United States which have been heavily settled by these nationalities. Although the world incidence of hydatid disease is highest in Australia, New Zealand, Uruguay and Argentina, the number of immigrants from these countries has been relatively small and they have not contributed appreciably to the incidence of the disease in North America.

There are no significant endemic foci of echinococcus disease in the United States, and less than twenty-five human cases have been reported in which the infestation is believed to have been contracted in this country.

Consequently, the possibility of echinococcus disease may be practically excluded in any person who has resided in the United States from birth. Although Riley⁷ has recently reported that a cycle of infestation with *Echinococcus granulosus* exists among moose and timber wolves in Minnesota, such a focus of infestation would not seem likely to be of consequence as regards a considerable extension of the disease to man or other animals. Furthermore, the low incidence of hydatid cysts found in sheep, cattle and hogs on this continent,⁸ together with the fact that dogs rarely have access to the viscera of slaughtered animals, also makes it unlikely that hydatid disease in our native population will ever increase significantly.

CLINICAL DIAGNOSIS

The diagnosis of echinococcus disease by means of routine clinical and laboratory methods is usually difficult. It is important to bear in mind the natural distribution of cysts, well illustrated by table 1 (from Dève⁹).

Since the liver and lungs are predominantly involved, echinococcus disease becomes a problem chiefly in the differential diagnosis of abdominal and pulmonary disorders. The symptomatology is in no way characteristic, and the disease may readily simulate hepatic cirrhosis, cholecystitis and cholelithiasis, abscesses of the liver

TABLE 1.—Location of 2,700 Cysts Found in Human Beings

and lungs and various new growths arising in the chest or abdomen. For a complete discussion of clinical manifestations the reader is referred to the articles of Dew¹⁰ and Godfrey.¹¹

Rupture of cysts occurs not infrequently and may be followed by severe or even fatal anaphylactic reactions. Ruptured cysts of the liver, as well as of the lungs, may discharge their contents through the bronchi, in which case "grape skins" or the characteristic hooklets may appear in the sputum.

Old, degenerated cysts frequently undergo calcification, in which case they may be readily detected by x-ray examination and present a typical appearance.

Eosinophilia is found in only 20 to 25 per cent of cases.

IMMUNOLOGIC REACTIONS IN DIAGNOSIS

The cutaneous test of Casoni¹ and the complement fixation reaction of Ghedini² and Weinberg³ are generally recognized as almost indispensable aids in the diagnosis of echinococcus disease. These tests each utilize hydatid fluid as antigen and are commonly supposed to be specific. The Casoni test consists of the intradermal injection of from 0.1 to 0.5 cc. of pheno-

lated hydatid fluid, which provokes allergic reactions of the immediate "wheal and flare" type in the majority of persons suffering from hydatid disease. The Ghedini-Weinberg test is carried out in the same manner as the Wassermann reaction. Fairley and Kellaway,¹² who have had extensive experience with both of these procedures in Australia, obtained positive reactions in about 85 per cent of proved cases. These authors consider the cutaneous test to be somewhat more sensitive than the complement fixation reaction.

While both cutaneous testing and complement fixation are widely employed in countries where echinococcus disease is common, neither has been employed in the United States to any extent because of the scarcity of hydatid fluid. Not only is hydatid fluid difficult to obtain,⁸ but different samples show wide variation in antigenic potency, while all specimens deteriorate more or less rapidly even though carefully preserved.

The observations of Morenas¹³ and Outeiriño¹⁴ and more recently those of Chung and Tung¹⁵ suggest that

SOURCE AND PREPARATION OF ANTIGENS

Cysticercus pisiformis is the larval stage of the dog tapeworm *Taenia serrata* and occurs naturally in the rabbit. From 10 to 50 per cent of stock laboratory rabbits are found to be infected with this parasite. The older animals show the higher incidence of infestation. The cysts are usually found in the omentum, about the gastrohepatic ligament or at the root of the mesentery.

The abdomens of healthy adult rabbits are opened with sterile precautions and searched for cysts. When these are found they are removed to Petri dishes, where the adventitial envelope, which is composed of rabbit tissue, is teased away with sterile dissecting needles to deliver the larvae. Ten or twelve of the larvae are triturated in a sterile mortar with 5 cc. of physiologic solution of sodium chloride containing 0.5 per cent phenol. The resulting suspension is allowed to extract for two hours at 37 C. The material is then centrifuged at high speed until no more sedimentation occurs. The supernatant fluid is pipetted off and portions are cultured aerobically

* Intensity of reactions was interpreted according to the size of the cutaneous wheal at twenty minutes, as follows: 1.0 cm. or smaller, negative; from 1.1 to 1.4 cm., +; from 1.5 to 1.9 cm., ++; from 2.0 to 2.4 cm., +++, and 2.5 cm. or larger, +++++.

the Casoni and Ghedini-Weinberg reactions are not species specific, as was formerly supposed, but are actually group specific. These investigators obtained allergic cutaneous tests and positive complement fixation reactions in known cases of hydatid disease when antigens prepared from other cestodes were substituted for hydatid fluid. In a previous communication¹⁶ we reported similar results in four cases of echinococcus disease in which cutaneous tests were made with a saline extract of the common rabbit cestode *Cysticercus pisiformis*. Further experiences obtained with this rabbit *cysticercus* extract, and observations on the use of a new antigen prepared from *Taenia taeniaeformis*, indicate that these antigens may be used as substitutes for hydatid fluid in the Casoni and Ghedini-Weinberg tests.

and anaerobically to determine sterility. The final product is a faintly opalescent liquid which does not settle out on standing and which contains approximately 75 mg. of nitrogen per hundred cubic centimeters. If the solution as originally prepared is found to be contaminated, it may be sterilized by the Arnold method.

Taenia taeniaeformis is an adult tapeworm found in the intestine of cats and is very common in this animal. The worms may be readily procured in laboratories where cats are maintained as stock animals.

The worms are washed thoroughly in running water, after which 0.5 Gm. of moist worm is triturated with 5 cc. of phenolated saline solution and the extract completed by the method already described for *Cysticercus pisiformis*.

The antigens thus prepared may be conveniently dispensed in ampules containing one cutaneous test dose and may be stored at least six months without loss of potency.

CUTANEOUS TESTS WITH SUBSTITUTE ANTIGENS IN PATIENTS WITH ECHINOCOCCUS DISEASE

Cutaneous tests have been performed on fourteen patients¹⁷ suffering from echinococcus disease, of whom

17. Assistance was given by Dr. Allen O. Whipple, Dr. Tasker Howard, Dr. C. F. Warren and Dr. C. F. E. Blunck, New York; Dr. John F. Kessel, Los Angeles, and Dr. O. R. McCoy, Rochester, N. Y.

nine were women and five were men. The patients ranged from 30 to 59 years of age. Twelve of the cases occurred in natives of foreign countries where hydatid disease is endemic, while both of the remaining patients, although born in the United States, had resided for considerable periods of time in either Argentina or Australia.

Echinococcus cysts of the liver were present in all of the fourteen patients. Pulmonary cysts were also demonstrated in two of the cases, and cysts of the peritoneal cavity were found in two others.

The cutaneous tests were carried out by injecting 0.1 cc. of the antigens intradermally on the volar surfaces of the forearms. Positive reactions (shown in the illustration) were characterized by wheals, which began to form in less than five minutes and reached their maximal size in from fifteen to thirty minutes. The wheals varied in size from 1.5 to 5.4 cm. in diameter, with pronounced pseudopodia, and were surrounded by zones of erythema from 5 to 15 cm. in diameter. The patients usually complained of more or less severe itching at the sites of the reactions. Fading of the reactions was complete in about twelve hours, although some residual induration usually persisted from twenty-four to thirty-six hours.

Control cutaneous tests with the antigens were performed on ten normal men and ten normal women and also on a series of twenty-five patients suffering from various nonparasitic pulmonary and abdominal disorders. The reactions in the controls were invariably negative, with cutaneous wheals not exceeding 1 cm. in diameter, no pseudopod formation and no residual induration at the sites of inoculation.

The results of the cutaneous tests of the patients with echinococcus disease are summarized in table 2. Strongly positive immediate reactions were obtained in ten cases, in five of which cutaneous tests were made with *Cysticercus pisiformis* antigen, in three with *Taenia taeniaeformis* antigen and in two with both antigens. The cutaneous wheals in these ten cases varied from 2.5 to 5.4 cm. in diameter, and all of the reactions were considered to be 4 plus.

Positive cutaneous reactions of moderate intensity were obtained in two cases, in one of which *Cysticercus pisiformis* antigen was used for testing and in the other *Taenia taeniaeformis* antigen. The cutaneous wheals in each of these cases were 1.5 cm. in diameter, and the reactions were read as 2 plus. In the remaining two cases, in both of which tests were made with *Taenia taeniaeformis* antigen, the wheals failed to exceed 1 cm. in diameter and the reactions were obviously negative.

Seven of the fourteen patients, all of whom gave strongly positive reactions with the *Cysticercus pisiformis* antigen, were also given cutaneous tests with hydatid fluid obtained from a fertile human cyst. The reactions obtained with the hydatid fluid were in each case somewhat less vigorous than those obtained with the substitute antigen, the wheals ranging from 2 to 3.5 cm. in diameter. The explanation for the less intense reactions obtained with hydatid fluid, as compared with those produced by the substitute antigen, is undoubtedly that the concentration of antigen in the hydatid fluid was lower than in the saline extract of *Cysticercus pisiformis*.

The results of the cutaneous tests in this series of fourteen patients indicate not only that positive reactions may be elicited by substitute antigens but also that a patient's cutaneous reactivity depends to a con-

siderable degree on the status of his disease. Thus all the strongly positive cutaneous reactions were observed in individuals who had had cysts previously removed or in whom rupture or suppuration of the cysts had occurred. The patient with uncomplicated cysts gave only a moderately positive reaction, as did one of the patients with calcified cysts, while the reactions of the other two patients with calcified cysts were completely negative. These observations agree with those of Fairley and Kellaway,¹² who reported that the Casoni test was frequently negative in patients with degenerated, calcified cysts and that patients with uncomplicated cysts frequently had cutaneous reactions of less intensity than those in whom suppuration, leakage or actual rupture of the cysts had taken place.^{17a}

COMPLEMENT FIXATION REACTIONS WITH SUBSTITUTE ANTIGENS

Tests¹⁸ made thus far indicate that the substitute antigens already described may be employed in the complement fixation reaction for echinococcus disease, as well as in the cutaneous test. The serums in seven proved cases of hydatid disease have been examined by this method with the saline extract of *Taenia taeniaeformis* as one of the antigens, in addition to three specimens of hydatid fluid from cysts of hog, sheep and man. The results of the tests, including those obtained with three control serums, are shown in table 3. When the substitute antigen was used, complete fixation of complement

Typical cutaneous reaction in a patient with echinococcus disease following the intradermal injection of 0.1 cc. of an antigen prepared from *Cysticercus pisiformis*.

was obtained with the serums of six patients and strong fixation with the serum of the remaining patient. These results compare with those obtained with the hog hydatid fluid and are superior to those found with the other two hydatid antigens. Anticomplementary action was not observed with any of the antigens.

COMMENT

Taxonomically, *Cysticercus pisiformis* and *Taenia taeniaeformis* are closely related to *Echinococcus granulosus*, since all are cestodes of the family Taeniidae. The results of this investigation indicate that these parasites bear a close antigenic as well as morphologic relationship and confirm similar observations which have been reported by Chung and T'ung,¹⁵ Morenas¹³ and Outeiriño.¹⁴

The Casoni and Ghedini-Weinberg reactions are apparently group specific, rather than species specific, and the antigens which we have described may therefore be substituted for the hydatid fluid commonly supposed to be required for these tests. These substitute antigens

17a. We have recently observed an additional patient with uncomplicated hydatid cysts of the liver, in whom 4 plus cutaneous reactions were obtained with both antigens.

18. Dr. Annis E. Thomson, of the New York City Department of Health, performed these tests.

are easy to prepare and are readily available, in contrast to hydatid fluid, which is difficult to obtain in this country.

Because of the group specificity of these reactions, tests performed with *Taenia* antigens may be expected to yield positive results in all types of tapeworm infestations in man. This has actually been shown to be the case for *Taenia saginata* by Outeiriño and for *Taenia solium* by Chung and Tung. However, echinococcus disease is the only common *Taenia* infestation in which the human being plays host to the larval stage of the

* The complement fixation tests were carried out with the usual Wassermann technic. Details of the procedure are omitted for the sake of brevity.

parasite, and infestation with the intestinal forms of taenias may be ruled out by careful stool examinations. Such examinations of the stools have been made in the cases of hydatid disease which we have already reported.

Positive cutaneous reactions were elicited with substitute *Taenia* antigens in twelve out of fourteen cases of echinococcus disease. The incidence of positive reactions is thus 85 per cent, which is similar to the results obtained by Fairley and Kellaway¹² with the classic Casoni test. The results of complement fixation tests with the serums of seven patients with known hydatid disease also furnish evidence that immunologic reactions for the diagnosis of this disease may be obtained as readily with substitute *Taenia* antigens as with hydatid fluid itself.

SUMMARY

- 1. Cutaneous tests with substitute antigens were performed on fourteen patients with echinococcus disease. Complement fixation tests were made on seven patients.
- 2. The group specificity of the Casoni and the Ghedini-Weinberg reactions was confirmed.
- 3. Readily available antigens may be substituted for hydatid fluid in either the cutaneous test or the complement fixation reaction for the diagnosis of hydatid disease.

Bad Habits Live on Dividends.—A child never clings to any habit, either in actions or in emotions, unless the habit brings a gratifying reward. . . . How long will a healthy baby hold to the habit of crying at night? Only as long as he "feels" that crying means being picked up, or being fed, or getting some other special attention. . . . How long will a child continue to have tantrums? As long as he feels that a tantrum will produce a slice of cake, the achievement of some other desire, or the reversal of some unpleasant parental command.—Hohman, Leslie B., *As the Twig is Bent*, New York, Macmillan Company, 1940.

Clinical Notes, Suggestions and New Instruments

CLEAR LIQUID MEDIUMS FOR THE "AEROBIC" CULTIVATION OF ANAEROBES

JOHN H. BREWER, PH.D., BALTIMORE

Anaerobic organisms are often overlooked in clinical and biologic laboratories because of the lack of a simple anaerobic medium which can be used just as any aerobic broth without the use of anaerobe jars or other special equipment or technics. It is well known that most clear liquid mediums when heated to drive out the air will be anaerobic for a short time. Whether this period is long enough to allow germination of the spores or growth of the anaerobes present depends on the composition of the medium, the amount of aeration while inoculating and several other factors. For most purposes the period of anaerobiosis obtainable in this manner is not sufficient. To avoid the use of mechanical devices such as the marble seal, special tubes or layers of oil or petrolatum, various substances have been added in attempts to prolong the anaerobiosis and still have a clear liquid medium which can be used like any aerobic broth.

Many clear liquid mediums have been suggested for the cultivation of anaerobes in open tubes. Most of these have been dependent on the addition of some compound containing the SH group for lowering the oxidation reduction potential. Among those suggesting such mediums were Trenkmann¹

Tube 1, the medium one week after sterilization. The darkened layer at the surface shows the aerobic portion of medium; the rest of the tube is anaerobic. Tube 2, the medium one month old. Note that, although evaporation rings are visible, the greater portion of the medium is still anaerobic. the work of the others and added several thio acids to the list. These mediums have not been generally accepted for various reasons. In order to get growth in most of them it is necessary to inoculate very soon after sterilization; in others, some of the components must be added aseptically just before use, and in still others the ingredients are expensive and difficult to prepare. The greatest handicap to the general acceptance of

these mediums has been their short duration of anaerobiosis. From three to four days is the maximum period that any of them will remain anaerobic; in most of them the period is only a few hours.

A medium which obviates these difficulties was devised without knowledge of the previous work with thioglycollic acid.

To the basic medium 1 per cent dextrose and 0.0002 per cent methylene blue were added, the dextrose to serve as an enrichment and the methylene blue as an oxidation reduction potential indicator. It has been found that this small dye concentration (1:500,000) is nontoxic and exhibits no bacteriostatic action against any of the many organisms employed. For some purposes the presence of 1 per cent dextrose is objectionable. In such cases the concentration may be reduced or the dextrose omitted entirely. Dextrose is of value in promoting the growth of many organisms and serves to prolong the anaerobiosis. Serum or ascitic fluid may be added to the medium aseptically if desired.

The medium was placed in 15 cc. amounts in 6 by three-fourths inch test tubes, making a column of medium 7 cm. high. It was then autoclaved for twenty minutes at 120 C. and stored at room temperature. (The medium should not be stored in a refrigerator, since a lower temperature increases the solubility of atmospheric gases and decreases the duration of the anaerobiosis.) Tubes of the medium were checked daily to determine the anaerobiosis and, except for a surface layer, the medium remained anaerobic for more than one month and supported growth from small inoculums of spores of some of the most strict anaerobes, including *Clostridium novyi*, tetani,

* The entire tube was slightly colored, indicating partial aeration throughout medium.

† 70 mm. of aeration indicates entire tube aerobic.

In testing the sterility of ampules of sodium antimony thioglycollate it was noted that a medium containing methylene blue decolorized on the addition of this product. Since antimony compounds are known to be toxic to some organisms, a medium containing sodium thioglycollate was made. The basic formula is given in the accompanying list.

Hitchens,⁶ Spray,⁷ Falk⁸ and others have shown that small numbers of organisms grow much more readily if fractional percentages of agar are used and, since this medium was developed as a sterility test medium, 0.05 per cent agar was included. It is realized, of course, that even this small percentage of agar lessens convection currents, thereby prolonging the anaerobiosis obtained without noticeably affecting the fluidity of the medium.⁹ Several anaerobic mediums have been based on this principle.¹⁰

septique, botulinum, welchii, sporogenes and several strains of anaerobic streptococci. In every case the growth was equivalent to that obtained in controls in anaerobic jars. It is not necessary to handle the medium with more care than is given the usual aerobic mediums. The tubes may be rotated after inoculation to distribute the inoculum and, although the medium will become colored, it clears in a few minutes except for the surface layer.

Some effort has been made to find an explanation for the seemingly reversible reaction taking place in the medium, but no definite conclusion has been reached. It has been found that 80 cc. of sterile air per minute can be bubbled through a tube of the medium for thirty minutes, and it will still support growth of *Clostridium novyi*, one of the most strict anaerobes.

Several mediums were prepared to determine the value of the different components in the medium from the standpoint of anaerobiosis. Results of these tests will be found in the accompanying table.

It was found that the same results could be obtained when thioglycollic acid was used instead of the sodium thioglycollate if the *pH* was readjusted. Thioglycollic acid is unstable after exposure to the air, so that it cannot be kept on hand very long without decomposition and, as Quastel and Stephenson have pointed out, it is a syrupy liquid and is difficult to handle. Sodium thioglycollate, on the other hand, is a relatively stable powder and may be readily weighed and dispensed.

To test the keeping qualities of such a medium, it was prepared in a dehydrated form for me by the Baltimore Biological Laboratory. Medium made from this powder, which had been kept several months, was found entirely satisfactory for the cultivation of the organisms previously mentioned.

A study has been made of the general utility of this medium. It is unnecessary to use Smith fermentation tubes or other special equipment. It need not be heated immediately before use and it has the advantage over a cooked meat or tissue medium that it is clear and that growth can be noted at once without staining. The sodium thioglycollate combines with and inactivates most of the mercurials used as preservatives, and one is much more likely to obtain growth from contaminated biologicals which are preserved with one of these highly bacteriostatic compounds. The anaerobiosis lasts much longer than the seven day incubation period required by the National Institute of Health for testing the sterility of biologic preparations or the fourteen day period required by the British Therapeutic Substances Act for catgut sutures and similar material. This medium might be called a facultative medium, since it supports not only growth of the most obligate clostridia but microaerophiles and aerobes as well.

A study of the utility of sodium thioglycollate for other bacteriologic purposes forms the basis for an additional publication.

NICOTINE POISONING IN A CHILD

RICHARD W. CRAGG, M.D., AND ARNOLD E. OSTERBERG, Ph.D.
ROCHESTER, MINN.

Nicotine is one of the most lethal poisons known to man. Some conception of its extreme toxicity may be gained by comparing it with hydrocyanic acid, which is of approximately equal potency. Nicotine is present in appreciable quantities in tobacco (ranging from 0.6 to 8 per cent),¹ the poorer grades containing relatively more than the better grades. Since tobacco is used so widely both for smoking and for chewing (including snuff), it is amazing that so few instances of fatal poisoning from nicotine have been recorded. As far as smoking is concerned, a possible explanation may be the destruction of the drug by combustion and also its expulsion with the smoke. Then too, marked tolerance acquired by the habitual use of tobacco is undoubtedly an important factor. Consequently, in a majority of instances nicotine poisoning among adults has been traced to the ingestion of some strong solution of the drug, usually an insecticide, and in the older literature it has been due to concentrated infusions made by boiling tobacco in water. On the other hand, children have no acquired tolerance to tobacco, as almost every male adult can distinctly recall. As a result, severe and even fatal poisoning may result from the smoking or chewing, and especially the swallowing, of tobacco in any form. Nevertheless the total number of reported cases of nicotine poisoning is small. Franke and Thomas² were able to find reports of only seventy and added four of their own, and Beeman and Hunter³ noted that through 1934 the Department of Commerce, U. S. Bureau of the Census, classified only 288 deaths as due to nicotine and its compounds. They also reported twenty-four cases from their own records. Moreover, the incidence among children has been even more rare; Willis⁴ was able to find only eight cases, including one which he himself observed. Of all forms in which nicotine has been ingested, tobacco in the form of snuff appears to have been the rarest cause of poisoning. We could find only two such reports. McNally¹ cited the case of Fontanelle, who in 1836 described the death of the French poet Santeul following the drinking of wine in which Spanish snuff had been placed.

Gonzales, Vance and Helpert (1937)⁵ stated that "death has occurred after swallowing 0.8 gram of snuff."

The case that we report is one in which snuff is believed to have been the poisonous agent and in which such a substance was ingested by a child.

REPORT OF CASE

A boy aged 4½ years, who had never been seriously ill, during the afternoon of November 19 was suddenly seized with a severe attack of nausea and vomiting, and his mother said that he "felt feverish." The symptoms partially abated after about an hour, but because he continued to show marked lassitude he was kept in bed and did not eat anything until noon of the following day. His parents did not recall that he even drank any water. By the following noon he felt better and for the first time drank some tea and orange juice. Approximately fifteen minutes after the ingestion of these liquids he was seized by a generalized tonic spasm. Opisthotonos was not present, but his mother said that "every muscle in his body was drawn tight." Following the onset of this convulsion, the breathing was at first very rapid and then ceased entirely. The spastic state continued uninterrupted until death intervened approximately twenty minutes later. As far as could be ascertained, cyanosis was present but its intensity was uncertain.

Necropsy was performed one and a half hours after death. The ventricles of the heart were markedly dilated, probably because of the asphyxial type of death. The stomach contained 30 cc. of thick yellow liquid and the mucous membrane was covered by a thick yellowish white coating, which could be scraped off only with great difficulty. The brain appeared edematous but its weight was within normal limits. An incidental finding of unusual interest was a very large polyp in the descending colon, which measured 3 by 1.7 by 1.5 cm. and was suspended on a pedicle 1.7 cm. long.

Microscopically, the wall of the stomach was the seat of marked inflammatory changes. There was a loss of almost all the specific secretory mucosal cells with replacement by masses of lymphocytes and reticular and fibrous tissue cells. The mucus producing cells appeared to be making feeble attempts at regeneration, and the muscularis mucosae was partially disorganized and moderately thickened. The surface of the mucosa was frankly necrotic and was covered by a heavy layer of fibrin and cellular debris in which were embedded lymphocytes and polymorphonuclear leukocytes. Microscopic sections of the polyp in the colon revealed masses of large columnar cells with hyperchromatic nuclei; the cells were piled up in great profusion. They were roughly arranged in papillary projections which extended out in all directions from a central stalk. The entire polyp had the appearance of a low grade carcinoma, but the hyperplastic changes were limited to the polyp itself and did not extend down the pedicle.

Since the child had been living on a small farm, we suspected that he might have swallowed some type of insecticide containing strychnine. The gastric contents were therefore analyzed by one of us (Osterberg) for this substance, but no trace of it was found. The remainder of the gastric contents was then extracted with ether from an alkaline solution and the presence of an alkaloid was determined qualitatively by the fact that precipitates were obtained with phosphomolybdic acid and potassium mercuric iodide. The residue from the evaporation of a portion of the ether had a slight odor of tobacco, which led to a further search for the possible presence of nicotine. This base was identified qualitatively by the fact that the residue yielded a positive test with Schindelmeyer's reagent of formaldehyde and nitric acid, a rose-red color being produced. Steam distillation of an additional aliquot of the ether extract yielded a precipitate with silicotungstic acid, which, while not a quantitative test, seemed to be conclusive evidence that we were dealing with nicotine. Quantitative measurements were not possible, but the strong positive evidence obtained by this analysis led us to postulate that the dose of nicotine was sufficient to be lethal.

5. Gonzales, T. A.; Vance, Morgan, and Helpert, Milton: *Legal Medicine and Toxicology*, New York, D. Appleton-Century Company, Inc., 1937, p. 580.

With this substantial evidence at hand, confirmation was sought by further interviews with the child's parents. In many of the cases of nicotine poisoning recorded in the literature the poisoning has been due to some insecticide, usually "Black Leaf 40," which is a solution containing 40 per cent of nicotine sulfate. Such a substance might have been used on a farm, but the parents denied possession of a chemical spray of any kind. At this point the child's mother voluntarily remarked that two weeks before the onset of the last illness the boy had experienced a sudden attack of nausea and vomiting, and at that time he admitted that he had chewed the dregs scraped from a discarded box of snuff. Although she did not know definitely whether the child had eaten snuff again, she said that no other form of tobacco was used at home and, owing to the similarity of the two attacks of vomiting, she was certain that snuff must have been the causative agent. We therefore believe that we are warranted in assuming that snuff was the actual form in which the nicotine was ingested, even though absolute proof of this association was not obtainable.

COMMENT

The classic signs and symptoms of nicotine poisoning, as described by Cushny,⁶ are salivation, nausea and vomiting, rapid respirations, a slow pulse followed by a rapid pulse, mental confusion, muscular weakness, vertigo, loss of coordination and loss of consciousness. Later, clonic convulsions may occur; these may be followed by fibrillary muscular twitching and finally by tetanic spasm, with death due to arrested respiration. Sometimes the victim may pass quickly into a state of complete collapse with loss of all reflexes and without convulsions. That these symptoms may occur only in part or in any combination is attested by a large number of the reported cases. In most of them there was nearly always onset of nausea and vomiting. Mental confusion and loss of consciousness were most frequently observed in those cases in which some concentrated solution of the drug had been ingested. Franke and Thomas,² in experimenting with dogs, noted that when convulsions occurred they were tonic in type and death was caused by fixation of the respiratory muscles. Because our patient died before the arrival of a physician, we were unable to ascertain the state of the pulse, but the mother's story was very definite as to the sudden onset of nausea and vomiting, and in the first and final stages she noted that the child breathed rapidly. No mental confusion or loss of consciousness was observed until the terminal spasm twenty-four hours later, but muscular weakness was obvious throughout. The final convulsion was apparently tonic in type, and death probably resulted from fixation of the respiratory muscles. The fact that spasm did not develop immediately must mean that in the beginning only a part of the nicotine contained in the ingested snuff was absorbed. The next time that fluid was swallowed was twenty-four hours later, and at that time a generalized tonic spasm developed within twenty minutes, with fixation of the respiration and death. This sudden incident suggests that a large part of the snuff was retained in the stomach and that when the fluid was ingested one of two things occurred: either the nicotine was rapidly dissolved and absorbed in the stomach or the snuff was suddenly washed into the duodenum, where rapid absorption took place. It would be too presumptive to say that the inflammatory changes which were observed in the gastric mucosa interfered with the absorptive power of the stomach, but the possibility must be considered. The inflammatory changes were both acute and chronic, and we suspect that they may have resulted from the irritative action of the snuff, the chronic changes representing a healing stage of the irritation caused by the previous ingestion of this substance and the acute changes by the recent ingestion.

According to the published accounts,³ death caused by nicotine poisoning usually occurs within an hour of the time the poison is drunk and often within thirty minutes. However, the victims almost always swallowed some concentrated solution of the drug. On the other hand, those persons who were poisoned by weaker solutions of tobacco often reacted in a manner similar to our patient, by living a day or more. The Frenchman previously mentioned,¹ who drank wine containing snuff, lived three days.

In only one of the twenty-four cases reported by Beeman and Hunter² did the poisoning result from an infusion of tobacco; this patient lived seven hours. Incidentally, they referred to the presence of hemorrhagic gastritis, which was found at necropsy in several of their cases. Price's⁷ patient was only 8 years old, and even though she drank an insecticide she lived three days. Price felt that the delay in the production of death was due to poor absorption. McNally¹ reported a case in which a young child died three days after blowing bubbles from an old tobacco pipe.

McNally stated that one cigar contains enough nicotine to kill two adults if injected directly into the circulation. He also quoted two instances in which people died within five minutes after eating between 1 and 2 ounces (30 to 60 Gm.) of tobacco. Another man died a few hours after taking an enema of water which had been previously boiled with 1 drachm (4 Gm.) of tobacco. Consequently it is obvious that if a child swallowed even a small amount of tobacco the result might readily be fatal. This undoubtedly explains why no gross tobacco particles were seen and no odor of tobacco was detected in the gastric contents of the child at the time of the necropsy.

SUMMARY

In the case of fatal poisoning which we have reported, evidence was obtained which circumstantially identified the fatal substance as snuff. Interesting postmortem observations, probably associated with the action of the poison, were acute and chronic inflammatory changes in the gastric mucosa. Another incidental finding of unusual note was a large polyp in the descending colon.

STAPHYLOCOCCUS AUREUS MENINGITIS SUCCESSFULLY
TREATED WITH SULFATHIAZOLE

FREDERICK W. DIETEL, M.D., CHURCHVILLE, N. Y.
AND
ALBERT D. KAISER, M.D., ROCHESTER, N. Y.

Staphylococcus aureus meningitis is an unusual type to occur in childhood, but when it does occur the mortality rate is high. In the few cases reported in the literature in which recovery has occurred, various methods of treatment had been employed. Since a new drug was used in the treatment of this case, it seems desirable to report it.

Norman M., aged 20 months, had no history of previous illnesses except for a furuncle on the upper lip several months before the present illness. The furuncle drained and healed, leaving a swelling the size of a small pea. Subsequent injury due to a fall causing a swelling about the lip and nose may have been the exciting cause of the present illness. A week following this slight injury on Feb. 18, 1940, the child became acutely ill with abdominal pain and distention and high fever. This was followed by drowsiness, rigidity of the neck and some vomiting. Lumbar puncture was performed on the third day of the illness. A thick, creamy looking spinal fluid was obtained which on smear and on culture showed hemolytic *Staphylococcus aureus* organisms. The blood culture taken on the third day showed the same organisms. There was no demonstrable focus of infection in the nose, throat or ears or in any other part of the body except the blood stream and meninges.

As soon as the bacteriology of the meningitis was established, medication was started. Sulfathiazole was administered by mouth through a stomach tube; 40 grains (2.6 Gm.) a day was given for nine days. Daily spinal punctures were performed with saline irrigations. Gradually the child improved, with a clearing of the spinal fluid and disappearance of the bacteria. At the end of three weeks there was complete recovery.

Numerous blood transfusions were given but no other drug was used. The sulfathiazole concentration of the blood never reached more than 3.5 mg. per hundred cubic centimeters of blood.

The only reactions to the drug were some vomiting and slight cyanosis. The child regained all his previous faculties and appeared to be entirely well two months after discharge from the hospital.

Special Article**THE PHARMACOPEIA AND THE
PHYSICIAN****THE TREATMENT OF MALARIA**

ALFRED C. REED, M.D.

Professor of Tropical Medicine, University of California Medical School
SAN FRANCISCO

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed.

In spite of the prevalence and long history of malaria and in spite of fairly efficient drug agents, ideas of treatment are noteworthy for their variance and their number.

PRINCIPLES OF TREATMENT

Drugs used in the treatment of malaria fall into four groups, which are plasmochin, atabrine, direct cinchona derivatives and a miscellaneous group, largely ineffective, insufficiently tested, empirical, experimental and even dangerous. Plasmochin and atabrine are chemically derivatives of quinine but for clinical purposes can best be considered separately.

1. Plasmochin is a synthesized substance, essentially an amino-quinoline, with the formula stated as (n-diethylamino-isopentyl-8 amino-6 methoxychinolin). It should never be given in a dosage exceeding 0.065 Gm. (1 grain) by mouth each day to an adult weighing 150 pounds (69 Kg.). In the form of a tablet, a third of the daily dose (0.02 Gm.) is given by mouth three times a day. Toxic symptoms easily appear in the form of cyanosis, pallor, nausea, gastric pain, headache, vertigo, weakness and hemoglobinuria. These depend to a considerable degree on the production of methemoglobinemia.¹ With the appearance of any such symptoms, the drug should be discontinued at once.

Action on the plasmodia of malaria is very unequal. It does not kill sporozoites. It is relatively ineffective on the trophozoites, or growing forms, especially of *Plasmodium vivax* of tertian and of subtertian malaria. Its greatest usefulness is in the destruction of gametocytes, or sexual forms, in tertian and especially in subtertian malaria. It therefore becomes an adjuvant of particular value in endemic areas where it is important to prevent infection of mosquitoes. It is not desirable as a sole treatment but serves a useful and limited purpose as an adjuvant to quinine. Because of its high toxicity, patients receiving it should be under constant close medical supervision.

2. Atabrine is another synthetic drug which has fully proved its usefulness. It is essentially an amino-acridine derivative (dihydrochloride of 2-methoxy-6-chlor-9-amino acridine). The therapeutic dose by mouth is well below the toxic range, so that it is fairly safe. It frequently causes yellow pigmentation of the skin, which usually clears within two or three weeks. The results of long continued or repeated pigmentation have not been well evaluated. Its average dosage for an adult of 150 pounds is 0.1 Gm. (1½ grains) three times a day by mouth for from five to a maximum of seven days.

It does not kill sporozoites. Its greatest effectiveness is on the schizonts, or growing forms, of *Plasmodium falciparum* in malignant subtertian malaria. In benign tertian malaria its action is similar to that of quinine but the relapse rate is lower. While it has some effect on gametes of benign malaria, like quinine it is relatively less effective against subtertian gametes of sexual forms. It has been used in the form of atabrine musonate for intramuscular injection. In this case the dose is 0.375 Gm. given only twice. There seems to be much greater toxicity with this compound, and its use is indicated only under unusual epidemic conditions. Atabrine itself is a yellow powder which easily dissolves in warm saline solution and can be given, therefore, intramuscularly. Such use is not advised except under unusual conditions as, for instance, when a patient is unduly sensitive to quinine or is in coma or has pernicious vomiting. Atabrine can be given safely by mouth without close medical supervision. It is of definite value both alone and in alternation with quinine.

3. Cinchona alkaloids are numerous and in general all are antiplasmodial in action. Quinine is the only one to be considered under ordinary conditions. The extracted residue, after removal of most of the quinine, is known as cinchona febrifuge and fills a useful place when the cost of quinine is prohibitive, but the febrifuge is of variable composition and therapeutic value. It is not necessary to discuss the other cinchona alkaloids further here.

In selecting the particular salt of quinine to be used, a balance is necessary between cost and solubility. For injection, the quinine dihydrochloride, quinine and urea hydrochloride or urethane solution (discussed later) should be selected as the most soluble salts, even though they are more expensive. The dose intravenously should not exceed 0.5 Gm. and may well be 0.3 Gm. For oral administration the bisulfate or the sulfate are most eligible, combining fair solubility with moderate cost, although the quinine content is relatively low in the former. The sulfate is cheaper but less soluble. Tablets that are made up with sugar or certain other excipients are prone to become stony hard and may pass through the intestinal tract unchanged. To meet this difficulty it is often advisable to administer the quinine in solution (prescription 1).

PRESCRIPTION 1.—Quinine in Solution

B. Quinine sulfate	0.3 Gm. (5 grains)
Aromatic sulfuric acid.....	0.4 cc. (6-8 drops)
Syrup of ginger, water, each in sufficient quantity	to make 4.0

Liquid prescriptions have the undesirable features of bitter taste, bulky content and difficulty of regular administration. For small children, however, they may be more usable than tablets or capsules. For a child the following method may be used: Dissolve a 5 grain (0.3 Gm.) tablet of quinine dihydrochloride in 4 teaspoonfuls (15 cc.) of water and add a little honey, syrup or jelly. One fourth of the solution contains 1¼ grains (0.08 Gm.) of the drug.

Capsules are not as desirable as tablets because they tend to melt in warm moist air and keep poorly. Plain tablet triturates of 5 grains (0.3 Gm.) each are best and should disintegrate quickly if dropped into a little water, although actual solution will not occur. Administration three times a day is much better than a single dose.

1. Bass, C. C.: Treatment of Malaria, with Some Reference to Recently Promoted New Remedies, J. A. M. A. 95: 988-992 (Oct. 4) 1930.

Quinine does not kill sporozoites. It is largely ineffective against gametes of *Plasmodium falciparum* in malignant malaria. It is only partially effective against schizonts, or growing forms. It does not prevent relapses which will occur in from 25 to 50 per cent of cases, no matter what dosage is given. These deficiencies would suggest that the dosage must be large and long continued, and such has been the prevailing belief and practice until the past few years. But cinchonism easily appears with large or continued doses, and some patients are so susceptible that quinine cannot be used at all. Moreover, it is found that excessive dosage does not increase the clinical effectiveness of quinine. Long usage gives decreasing therapeutic efficiency. Altogether it is now felt by many that quinine should be used relatively late in the course of malaria, as it has been known for a long time that it is ineffective during the incubation period and most effective after the first paroxysm, and even later as the parasites and fever are both beginning to decline and in relapses.

The Malaria Commission of the Health Organization of the League of Nations² built on these observations in recommending that in patients who have good individual medical supervision, treatment should be short in duration and aimed only at controlling clinical manifestations of the first attack and relapses. This would allow maximal development of immunity and utilize it to the fullest. This advice, however, should not apply at any time to malignant or subtertian malaria. Here the clinical danger is so great and constant that eradication of parasites should be the goal at the earliest possible moment.

4. Miscellaneous drugs have been recommended. Three groups of these can be separated off at once from the field of specific medication:

(a) Epinephrine, ergot (and quinine), heat, cold douches, alcohol, purges and nonspecific proteins have been urged as provocatives in latent malaria to contract the spleen and cause the appearance of plasmodia in the circulating blood, allowing certainty of diagnosis. Such measures are usually ineffective, may be dangerous and should not be used.

Reference may be made to Ascoli's³ method of treatment with increasing intravenous doses of epinephrine, beginning with 0.01 mg. and increasing each day to $\frac{1}{90}$ mg., $\frac{1}{80}$ mg. and so on respectively until the daily dose is 0.1 mg. The last dose is repeated daily for twenty days. In case of unusual splenomegaly, the dose is further increased if well tolerated. Numerous reports indicating considerable success in reducing the spleen of chronic malaria have appeared. This reduction in size of spleen is accompanied by improvement in the anemia. Ascoli's method has been used extensively in conjunction with quinine treatment, with reported favorable effect on length of treatment and lowered relapse rate in chronic malaria.

(b) Iron and various arsenic compounds have been found useful in the treatment of malarial anemia. Sometimes these have mistakenly been assumed to have antiparasmodial action.

(c) Arsenic in the form of neoarsphenamine is frequently advised and does have a partial effect on schizonts, chiefly of *Plasmodium vivax*, if given during the attack. Its low therapeutic value and its definite dangers contraindicate its use.

(d) Sulfanilamide, of course, has received considerable favorable attention in clinical reports. Coggeshall⁴ reports a high rate of cure and prevention in *Plasmodium knowlesi* infections in rhesus monkeys. Chopra and Das Gupta⁵ obtained similar results in monkeys, presumably of the rhesus variety, and jumped to the conclusion, not warranted by their experimental work, that sulfanilamide compounds are effective specific drugs for malaria in man. Coggeshall⁶ properly warns against assuming therapeutic efficiency in man on the basis of the effect in monkeys. Various clinical reports of cure of human malaria have appeared, but attention must be called to the four cases reported by Faget, Palmer and Sherwood⁷ in which sulfanilamide was ineffective and attended by certain dangers. These cases were completely hospitalized and carefully controlled. Use of sulfanilamide compounds in human malaria cannot be recommended until much further carefully controlled experimental evidence is available on human malarial plasmodia.

In addition, an endless array of medicaments have received the credit of causing benefit and cure without any valid controlled experimentation and often with no conception of their toxicity. Careful toxicity studies on animals and exact determination of safe human dosage must be followed by carefully controlled human administration in a large number of cases before a new remedy can safely be accepted for clinical usage. Disregard of this fundamental rule of chemotherapy has often led to disastrous results.

OBJECTS OF TREATMENT

The physician must consciously determine for each patient what is to be the object of treatment. Environment, expected change to different environment, contiguity of anophelines, residence in an endemic area, need of prevention of infection of mosquitoes, need of personal prophylaxis temporarily as on an expedition or for a long period if in residence, concomitant diseases and conditions, as for instance, pregnancy, all seriously influence the kind and duration of treatment to be selected. Further modification must be made also in accord with the variety of plasmodium present, the age of the patient and whether the attack is initial or recurrent. As has been stated, no drug is known which will destroy sporozoites. Therefore, true prophylaxis is impossible under any conditions. At the most, symptoms can be delayed or prevented by a systematic attack on schizonts, or growing plasmodia. No drug is known which will accomplish a *therapia sterilisans magna*. Therefore a partial objective must be set.

Finally, careful consideration must be given to the problem of developing and maintaining immunity, which is at times the best of all treatments. This is difficult in the case of the malignant subtertian type because of the constant clinical danger while the patient harbors plasmodia. And still complete eradication of plasmodia seems to terminate immunity. The patient is undoubtedly safer at present, however, with every effort directed at early plasmodial cure. In benign tertian and quartan malaria, immunity can be cultivated at times with safety and advantage to the patient.

APPLIED TREATMENT

1. For the average acute attack, initial or relapse, it is recommended that the patient receive atabrine 0.1 Gm. ($1\frac{1}{2}$ grains) three times a day by mouth for one week. If the patient is not to be subjected to probable reinfection and pernicious symptoms are lacking in the case of benign tertian or quartan infection further treatment can be postponed until relapse occurs. In the case of subtertian or malignant malaria the atabrine course should be followed by quinine sulfate 1 Gm. (15 grains) in three divided doses after meals on four consecutive days each week for six weeks. Patients weighing more than 160 pounds (72.6 Kg.) should receive 1.3 Gm. (20 grains) each day. In acute malignant or subtertian malaria the daily adult dose may be increased to 2 Gm. (30 grains) daily for two or three days. Children usually tolerate quinine well and, up to 1 year of age, can be given from 0.065 to 0.10 Gm. (1 to $1\frac{1}{2}$ grains) a day. For children from 1 to 12 years of age the dose should be from 0.1 to 0.8 Gm. ($1\frac{1}{2}$ to 12 grains) increasing with age. A valuable form of quinine, which is practically tasteless, is quinine ethylcarbonate, of which the dosage is the same as for the sulfate.

The comparison of quinine salts in table 1 shows the percentages of quinine, which is of some importance in selecting the relative dosages.

Quinine (basic) is only very slightly bitter, slightly soluble and absorbs well.

TABLE 1.—Percentage of Quinine in Various Quinine Salts

	Per Cent of Quinine
Quinine hydrochloride	81.7
Quinine dihydrochloride	81.6
Quinine sulfate	73.5
Quinine bisulfate	59.0
Quinine tannate	30.0
Quinine ethylcarbonate, approximately	40.0
Quinine and urea hydrochloride	58.0-65.0

In the presence of pernicious vomiting, coma or evidence of nonabsorption of the drug, quinine dihydrochloride or quinine and urea hydrochloride, or quinine hydrochloride and ethyl carbamate should be given intravenously, 0.5 Gm. ($7\frac{1}{2}$ grains) being the maximum dose. The rate of injection must be extremely slow, not faster than 1 or 2 cc. a minute, and interrupted at any sign of collapse. Ampules of quinine hydrochloride 0.13 Gm. and ethyl carbamate (urethane) 0.065 Gm. in 1 cc. of sterile water are standardized in the National Formulary. Two such ampules can be given as a dose and repeated in from four to six hours. Quinine dihydrochloride is easily soluble but is acid and easily causes necrosis if the intravenous injection is too rapid or if the solution escapes from the vein. Quinine and urea hydrochloride is less acid in solution than the dihydrochloride. A few drops of epinephrine solution can be added to the intravenous dose with advantage. Ampules of these two salts are also recognized in the National Formulary. Subcutaneous injection should never be used, and an intramuscular injection is undesirable.

In case of known idiosyncrasy to quinine, and in cases of small children in whom oral administration is not possible, intramuscular injection of atabrine is desirable. Two injections are to be given twenty-four hours apart, each consisting of a freshly prepared solution of 0.1 Gm. of atabrine in 3 cc. of distilled water, or 0.3 Gm. in 9 cc. of distilled water. The solution must be prepared immediately before injection. The atabrine is supplied in sealed ampules containing 0.1 or 0.3 Gm. The single

dose for children should take into account the age as well as the general condition. Nocht and Mayer⁸ recommend Simeons' advice in treating large numbers of patients in India (table 2). The two intramuscular injections are followed by oral administration for an additional period of five days.

TABLE 2.—Dosage of Atabrine According to Age

Age	Dose
From 6 months to 2 years	Approximately 1 cc.
From 2 years to 4 years	Approximately 2 cc.
From 4 years to 6 years	Approximately 3 cc.
From 6 years to 10 years	Approximately 4 cc.
From 10 years to 12 years	Approximately 5 cc.
From 12 years to 15 years	Approximately 6 cc.
From 15 years to 18 years	Approximately 7 cc.
Healthy men	0.3 Gm. in 9 cc.
Healthy women and weaker men	8 cc.
Weak or sickly women	7 cc.

Intravenous injections of atabrine can be given with the same standard solution, 0.3 Gm. in 9 cc. of distilled water, in similar or smaller doses. Such administration is less desirable than intramuscular injection of atabrine. I do not recommend the use of atabrine musonate.

Plasmochin should be administered only when it is important to destroy gametocytes, especially of malignant or subtertian malaria. The dose should not exceed 0.02 Gm. by mouth three times a day after meals and should never be given on an empty stomach. This is continued for one week, provided no cyanosis or other symptoms of toxicity, such as abdominal pain, appear. Patients should be under constant medical observation. Atabrine should not be given at the same time as plasmochin. Plasmochin should never be used alone for treatment of malaria. It can be given coincidentally with quinine.

2. Symptomatic treatment is highly important. Bed rest is desirable. Purgation to the extent of keeping the bowels open is extremely valuable. Vomiting is often a distressing symptom and can be alleviated best by direct specific treatment. It may be lessened by carbonated waters or champagne, sweetened chloroform water, ice in the mouth and at times lavage.

PRESCRIPTION 2.—Iron and Arsenic Capsule

R Iron and ammonium citrate	0.25 Gm. (4 grains)
Carbarsone	0.065 Gm. (1 grain)
Quinine sulfate	0.03 Gm. ($\frac{1}{2}$ grain)

Mix and make one capsule.

Label: One capsule after meals three times a day.

Iron and arsenic preparations facilitate recovery from the anemia of malaria. Such a one as prescription 2 may be used.

Especially in children, sunbathing or ultraviolet treatments are valuable in late convalescence. Vigorous exercise, chilling, excitement, high altitudes, cold climates and all excesses must be avoided.

3. Chronic malaria and malarial cachexia constitute a difficult problem. Nocht and Mayer⁸ recommend a mixture of plasmochin and quinine sulfate for twenty-one days by mouth, three tablets after each meal. The dose for children from 1 to 5 years is one-half tablet once or twice a day and for those from 6 to 10 years one-half tablet three or four times a day. Each tablet contains 0.01 Gm. of plasmochin and 0.3 Gm. of quinine sulfate. This cannot be used in the presence of idiosyncrasy to quinine. Routine administration of quinine

8. Nocht, Bernhard, and Mayer, Martin: *Malaria, A Handbook of Treatment, Parasitology and Prevention*, ed. 2, London, John Bale Medical Publications, in German, translated into first English edition by Sir S. R. Christophers, 1937.

sulfate 0.3 Gm. (5 grains) two or three times a day for three or four days of each week can be continued for six weeks, in association with such a prescription as that for carbarsone, iron and ammonium citrate with caffeine citrate.

Splenectomy is often advised for malarial cachexia but authorities again do not agree.

4. Cinchonism is best treated by caffeine or coffee. Mild symptoms are common at the beginning of a course of quinine and require no treatment. In fact, lacking mild symptoms of cinchonism, one wonders whether the quinine is being well absorbed. It is often worth while to test sensitivity to quinine by giving a test dose of 0.6 Gm. (10 grains) before the subject goes to a malarial district. Some persisting fevers disappear at once if quinine is stopped, having been caused by the so-called paradoxical quinine fever. A hemorrhagic tendency may follow the use of quinine and may be distinguished with difficulty from hemorrhage due to malaria itself. The calcium level of the blood should be maintained by giving such a prescription as that for dicalcium phos-

PRESCRIPTION 3.—Iron and Arsenic with Caffeine Citrate

R̄ Carbarsone	0.065 Gm. (1 grain)
Iron and ammonium citrate.....	0.20 Gm. (3 grains)
Caffeine citrate	0.10 Gm. (1½ grains)
Mix and make one capsule.	
Label: Give one such capsule after meals three times a day.	

phate. Or 10 per cent calcium gluconate solutions, 10 cc. intravenously daily for from five to twenty days should be given. In all cases, atabrine must be promptly substituted for quinine if cinchonism appears.

5. In a case of pregnancy, miscarriage is prone to occur from malaria. Specific treatment should be adequately followed, as the possibility of stimulation of uterine contractions by quinine or other antimalarial drugs is much less than the probability of miscarriage from malaria.

6. Prophylaxis is another moot question with authorities. Since no known drug kills sporozoites, a true prophylaxis is impossible and the most to be accomplished is to limit or destroy schizonts, or growing forms of plasmodia. To this end various methods are in use. Quinine sulfate may be given, 0.3 Gm. (5 grains) daily or 1 Gm. (15 grains) in three or five divided doses, on one or two days of each week. Cinchonism and decreased antimalarial action often appear after long use

PRESCRIPTION 4.—Dicalcium Phosphate

R̄ Dicalcium phosphate	4 Gm.
Label: One teaspoonful twice a day, stirred up in a little water.	

of quinine. Atabrine may be given, 0.1 Gm. twice daily twice a week. Prophylaxis of this type is more apt to be useful on short trips than for those resident in endemic districts. The treatment should be continued for six weeks after termination of exposure.

FINAL NOTE

The reader is especially referred to the Fourth General Report of the Malaria Commission of the League of Nations Health Organization⁹ and to the small textbook by Nocht and Mayer,⁸ translated into English by Christophers.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.
HOWARD A. CARTER, Secretary.

PHYSICAL THERAPY IN ARTHRITIS

WITH SPECIAL REFERENCE TO HOME
TREATMENT

FRANK H. KRUSEN, M.D.

ROCHESTER, MINN.

There are three groups of physical measures which may be employed in the treatment of arthritis: The first includes the thermal measures (heat and cold), the second includes massage, manipulation and splintage, and the third includes exercise, postural training and rest.

Although physical treatment plays a very important part in the management of many types of arthritis, and although its employment has been enthusiastically advocated by many authorities on rheumatic diseases, nevertheless physical therapy should never be used to the exclusion of other therapeutic procedures. The physician who is confronted by a case of arthritis should, after establishing the diagnosis, map out a program which may include not only physical therapy but also psychotherapy, elimination of trauma, dietetic management, surgical removal of foci or other surgical measures, administration of vaccines, administration of analgesics and other drugs and climatotherapy.

Whereas it is possible to bring great benefit to the patient who has arthritis by the utilization of certain simple physical measures as a part of the home treatment, such procedures can be used to greatest advantage only when they are made a part of a well planned program of general treatment. It is essential, in establishing the diagnosis, that one have in mind a workable classification of the various forms of arthritis. There are almost as many such classifications as there are physicians specializing in the treatment of arthritis. No special grouping can be considered entirely satisfactory, and any classification which might be presented is open to criticism. One such list which has proved acceptable as a basis for general diagnosis and treatment is, in abridged form, as follows:

Traumatic arthritis: That caused by trauma.

Infectious arthritis: That caused by infections of known type (identifiable bacteria) and that possibly or probably caused by infections (unidentifiable or related toxins).

Degenerative arthritis: That caused by or characterized by degenerative changes in tissue.

Chemical arthritis: That whose chief (or only) obvious characteristic is a recognizable (or suspected) chemical derangement.

Neoplastic arthritis: That due to neoplasms, malignant or benign.

Miscellaneous: Miscellaneous and unclassifiable types.

This classification will be employed in the present discussion.

Once the diagnosis has been established and the disease properly classified, the physician may proceed to

the organization of a plan of therapeutic management. The employment of physical measures plays a very important part in any such plan. In support of this contention one need only refer to the statements of various outstanding authorities. For example, Fox and Van Breemen¹ said "... we rely to a great extent

Fig. 1.—A homemade baker for therapeutic use. Specifications are supplied and any electrician can make this at little cost.

on Physical Medicine." Copeman² spoke of the employment of physical methods as "one of the most important therapeutic advances made in this century." Hench³ wrote, concerning the treatment of arthritis, "Physical therapy remains the most potent single weapon at hand," and Pemberton and Osgood⁴ expressed the opinion that any discussion of arthritis should "develop, at length, the important field of physical therapy."

It is not essential to institutionalize a patient in order to apply physical treatment. There are many simple physical measures that can be applied in the patient's own home. Even when a patient with arthritis has been benefited by prolonged sessions of institutional physical therapy, such benefits may be lost promptly unless, on his return home, steps are taken to continue physical therapy as a home procedure. For example, the average patient who has atrophic arthritis is financially unable to continue indefinite hospitalization. It therefore becomes necessary to offer a substitute at home for the more elaborate routine of physical therapy in the hospital. An attempt will therefore be made to discuss the various types of arthritis from the standpoint of the main cause or characteristic, the general plan of management of such cases and especially with regard to the less complex physical measures which may be employed in the home as an extremely important phase in the treatment of arthritis and as a substitute for more elaborate hospital procedures. The physical measures will be described first, and then their applications in various forms of arthritis will be discussed.

SIMPLE PHYSICAL MEASURES WHICH CAN BE EMPLOYED IN THE PATIENT'S OWN HOME.

Thermal Agents.—In the management of arthritis, local or general application of heat may be of great value. Occasionally, but less frequently, applications of cold are indicated. Often alternate applications of heat and cold (contrast baths) are of value.

Heat: Heat is most readily applied in the patient's own home by means of some simple device.

Homemade baker. An inexpensive homemade baker (fig. 1) can be constructed which consists of a piece of ordinary sheet tin curved in a rooflike fashion on a framework of strap iron or rods. Two double electric sockets are attached to the under surface of the roof and the necessary wiring is installed. Bulbs of either 60 or 120 watts or a combination of these may be inserted into the four lamp sockets in order to obtain the desired amount of heat. Complete specifications for construction of this device are as follows:

It is 19 inches long, 19 inches wide, 16 inches high over all, supporting framework constructed of rod iron $\frac{1}{4}$ inch in diameter or $\frac{1}{16}$ by $\frac{5}{8}$ inch strap iron, reflector highly polished tin sheeting, two double receptacles (sockets), 250 volts, 650 watts, four 60 or 120 watt carbon filament lamps. The tin is rolled over the rod iron supports or is riveted to the strap iron; then the receptacles are connected in multiple with heavy lamp cord 6 feet long. A rubber plug is attached to the end of the cord. This baker is designed for applying heat to the legs, arms or body. If the baker is to be applied only to the legs or arms, the height may be only 14½ inches (36 cm.) at the highest point. If the baker is to be applied only to the trunk, the height may be increased to 18 inches (45 cm.).

Clamp lamps for home use. I have previously described in *THE JOURNAL*⁵ an inexpensive clamp lamp (fig. 2) which consists of a small cup-shaped

polished reflector, similar to those used in photography with "photo flash" bulbs. This reflector is attached by means of a ball and socket joint to a small rubber-covered clamp which may be fastened to the back of a chair, the edge of a table or the side of a bed. For therapeutic use, the reflector should contain a 250 watt Mazda CX bulb such as is manufactured by both the General Electric and Westinghouse companies. A 200 watt carbon filament bulb may be used, but it is not quite so satisfactory as is the CX bulb. In application, the lamp is placed at a distance of approximately 18 inches (45 cm.) from the part of the patient's body which is to be treated, and treatments should last for from thirty to forty-five minutes, usually administered

Fig. 2.—Clamp lamp suitable for applications of radiant heat in the home treatment of arthritis. The device may be clamped to the back of a chair or to the side of a bed.

5. Krusen, F. H.: A Simple Inexpensive Heat Lamp, *J. A. M. A.* 107:780 (Sept. 5) 1936.

once or twice daily. The employment of these luminous heaters (bakers or clamp lamps) is to be preferred to the use of the common electric heating pad.

Electric heating pads. These pads often become too hot for satisfactory local treatment and may cause cutaneous burns. The Council on Physical Therapy has discussed the need for warning physicians and their patients against the indiscriminate employment of these pads for therapeutic purposes. Hench⁶ has shown that the average low temperature of the ordinary household electric heating pad is approximately 107.6 F. (42 C.), the medium temperature, 181.4 F. (82 C.) and the high temperature 244.4 F. (118 C.). These temperatures are, of course, entirely too high for the local treatment of the average arthritic joint.

Hot paraffin packs. If electricity is unavailable in the patient's home, local applications of ordinary hot paraffin may be employed as a substitute for the simple radiant heat devices. Almost invariably the patient has in his home a stove and a double boiler, and he can obtain from the nearest grocery store some paraffin such as is commonly used by the housewife for sealing preserve jars. The lower pan of the double boiler is filled with water and the cakes of paraffin are placed in the upper pan. The paraffin is then melted and permitted to cool until a thin film has formed on its surface. At this time, when the paraffin is at its low melting point, it may be painted over the involved arthritic joint or other region with an ordinary paint brush or swab of linen on a stick. About twelve coats should be applied in rapid succession and this thick layer of paraffin is allowed to remain in place for from thirty to sixty minutes. Paraffin should never be applied over a hairy region without preliminary oiling or shaving. On rare occasions the patient's skin is sensitive to paraffin and a slight rash may be produced. At the end of the treatment the paraffin may be readily peeled away from the skin and returned to the double boiler for remelting and subsequent employment. The paraffin can be kept sterile by bringing the water in the boiler to the boiling point for several minutes.

A variation of this technic which can often be employed to advantage at home in the management of subacute inflammation of arthritic joints is to apply a dressing of alternate layers of gauze and paraffin. First a layer of paraffin is painted around the joint and this is encircled by a layer of gauze bandage. Another layer of paraffin is painted over the gauze and then the bandage is wrapped over this second layer of paraffin. These alternate layers of gauze and paraffin are applied in quick succession until a thick, firm, hot dressing envelops the entire joint. If the dressing is of sufficient thickness, it will remain hot for at least an hour. The dressing is then left on as a comfortable, firm support for a period of twenty-four hours; then the procedure is repeated.

Whirlpool baths. During the war of 1914-1918 there was developed by French army surgeons a device called the whirlpool bath which came into general use not only abroad but also in the centers for rehabilitation of disabled soldiers in this country. These whirlpool baths are now used extensively in many civilian hospitals and they have been found to be of considerable value for producing hyperemia in the extremities of patients suffering from various forms of arthritis. A simple whirlpool bath can be constructed

very cheaply for home use. The Council on Physical Therapy has prepared specifications for the construction of this device. Any plumber can make it at a cost of a few dollars by following the illustrations (fig. 3) and specifications.

Diathermy. Diathermy occasionally may be employed by the physician for treatment of arthritis at the patient's home, and small portable diathermy machines are available which can be taken to a patient's home. However, such machines should never be employed by the patient for self treatment, since much more harm than good is likely to ensue. Actually, diathermy is rarely needed for the treatment of arthritis, and simpler methods of applying heat will usually be found more suitable.

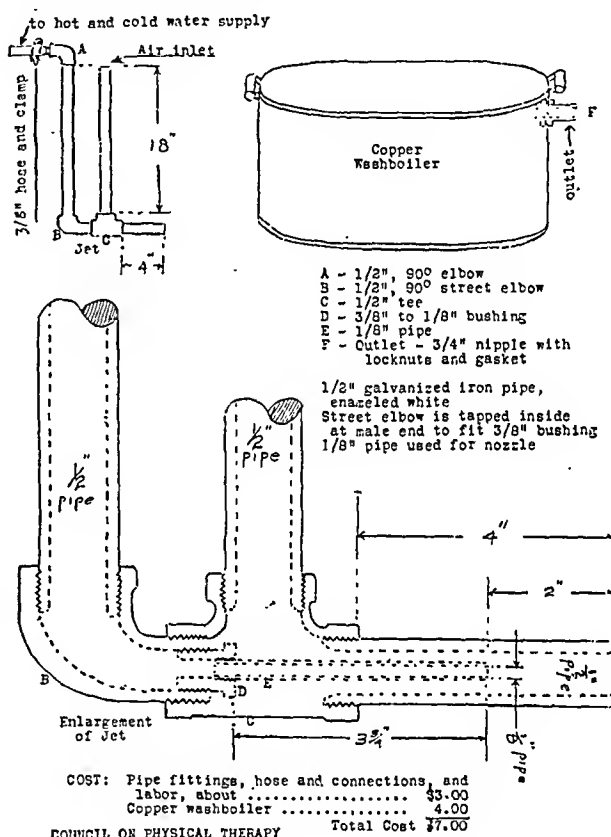

Fig. 3.—Specifications for whirlpool bath.

Heliotherapy. Occasionally patients with arthritis who are in poor general physical condition, undernourished and suffering from secondary anemia may be benefited by a series of exposures to natural or artificial sunlight. Such exposures tend to improve the function of the skin and stimulate metabolic processes. Exposures should be made judiciously under careful medical supervision. Employed with a sense of proportion in cases of arthritis in which it is indicated, general ultraviolet irradiation may be considered as a valuable auxiliary measure. If climate and home conditions permit exposure of the nude patient to sunlight, the best procedure is the method of insolation described by Rollier (fig. 4).

If it is not possible, because of weather conditions or other interfering factors, to expose the patient to sunlight, one may employ a small mercury quartz sun lamp at home for the production of artificial heliotherapy. For this purpose the so-called S-1 lamp

6. Hench, P. S., in discussion on Freund, H. A., and Watts, F. B.: The Treatment of Subacute Bacterial Endocarditis with Excessive Hyperpyrexia, in Abstracts of Papers and Discussions, Fifth Annual Fever Conference, May 2 and 3, 1935, pp. 87-88.

(fig. 5) may be very satisfactory. When this lamp is employed, it is usually applied at a distance of 2 feet from the bodily surface and exposures of five minutes over the upper half and lower half of the front of the body and then the lower and upper halves of the back of the body are made. Treatments are usually given three times a week, and the dosage is gradually increased

Fig. 4.—Rollier's schematic diagram of insolation including the method of progressive exposures of the patient to sunlight.

at each subsequent session until a maximum of thirty minutes over each area is reached. At no time should a marked sunburn be produced, but a mild erythema is permissible. If there is not too much erythema, the second exposure over each area may be for ten minutes, the third for fifteen minutes, the fourth for twenty minutes and so on. If there is too much reaction after any treatment, the dose should not be increased at the next session, and increases thereafter should be more gradual.

Tub baths. It has been found that in certain cases of atrophic arthritis very mild febrile reactions may tend to control an exacerbation of the disease. In institutional practice it is frequently customary to give short sessions of fever therapy in one of the elaborate cabinets now available for this purpose. These sessions usually last for thirty minutes, and the bodily temperature is usually raised to approximately 101 F. (38.3 C.). Such treatments are never administered to asthenic or debilitated patients except with extreme caution. However, for more robust patients the procedure may be very valuable. It is entirely possible, under proper medical supervision, to obtain exactly the same type of febrile reaction at home by placing the patient in his own bathtub. The temperature of the water may be varied between 98 and 105 F. (36.6 and 40.5 C.) and the duration may vary from ten to forty-five minutes. In some instances it may be advisable to increase the temperature of the water gradually during the bath. Usually the patient's oral temperature will rise in thirty minutes to approximately 101 F. (38.3 C.), sweating is induced and the general metabolism is stimulated. In all cases milder temperatures and shorter periods of time should be used at first, the temperature and duration being increased at subsequent sessions as tolerated.

The full wet pack. The usual method of applying a full wet pack may be employed to produce a mild circulatory reaction in patients who have arthritis. The first effect is to cause a contraction of the peripheral

vessels and an increase of the respiratory rate when the cold wet sheet used in the pack is applied to the skin. Within one to five minutes, however, after the patient has been wrapped in blankets, a "reaction" occurs, the cutaneous vessels dilate, and the patient becomes warm and begins to perspire rather profusely. The usual time of application of a wet pack is from thirty to sixty minutes. The exact technic has been well described by Coulter in the Handbook of Physical Therapy.⁷

Cold: Occasionally applications of heat are not well tolerated by a patient suffering from arthritis. This, however, is a rare exception, since in the vast majority of such cases the greatest relief is afforded by applications of heat. Once in a while local applications of cold may prove valuable to allay acute inflammation in joints.

Cold compresses. Cloths wrung out in cold water and applied directly over the joint for a period of from ten to fifteen minutes are occasionally used. Applications of ice bags and ice coils are usually not employed because the cold from these sources is too intense.

Cold baths. By proper timing and graduation of cold baths or showers, the arthritic patient who is sensitive to cold may be gradually made more tolerant to it. Likewise, brief cold baths or showers may be employed as a "metabolic whip." The patient who has arthritis and who is frequently abnormally sensitive to external cold may sometimes be benefited by the so-called hardening treatment (abhärtung), which consists of repeated applications of brief cold baths or showers. Usually during such brief baths, which should last for not more than one to five minutes, rapid friction is applied to the surface of the patient's body to stimulate a "reactive hyperemia." If this "reactive hyperemia" is not obtained and the patient is chilled and blue following such a brief application of cold, the degree of coldness should be diminished and the time shortened until the proper "warm and glowing" reaction is obtained. Thereafter, the intensity and duration of the cold bath or shower may be increased

Fig. 5.—S-1 lamp which may be employed for artificial heliotherapy in a patient's home.

slowly, a correct reaction always being obtained until the patient readily tolerates cold.

Heat and Cold: Contrast baths. Contrast baths (fig. 6) have been applied effectively for many years in the management of arthritis, particularly hypertrophic arthritis of the extremities. They are especially useful in the presence of cold and clammy extremities. The successive stimuli produced by alternations of hot and

7. Coulter, J. S.: Hydrotherapy, in Handbook of Physical Therapy, ed. 3, Chicago, American Medical Association, 1939, pp. 179-193.

cold tend to produce better and more rapid reactions day by day. When contrast baths to the hands or feet are to be employed at home, definite written instructions should be given the patient concerning the method of application. The patient should be told to obtain two buckets or pans of proper size and shape for immersion of the feet or hands. One container should be filled with hot water at comfortable tolerance, from 105 to 110 F. (40.5 to 43.3 C.); the other container should be filled with cool tap water, from 60 to 65 F. (15.5 to 18.3 C.). At first it was customary to immerse the extremities first in the hot and then in the cold water at one minute intervals, beginning and ending in the hot.

More recently, Woodmansey, Collins and Ernst⁸ have made extremely interesting studies on the employment of the contrast bath in cases of rheumatoid (atrophic) arthritis and have demonstrated that the usual practice of applying contrast baths for alternate periods of one minute each does not produce satisfactory responses. After a series of carefully controlled studies they found that the best reaction (active contraction and relaxation of blood vessels and increased flow of blood) is obtained when hot water is applied for six minutes and cold water for four minutes. The next best reactions were obtained with applications of hot water for seven minutes and cold water for five minutes. At the Mayo Clinic our attempts at confirmation of these observations have not been completely successful, possibly because our American patients are accustomed to warmer houses and a warmer environment than were the English subjects studied by Woodmansey⁸ and his associates. Our patients have tolerated such treatments when cold was applied for shorter periods of time not exceeding three minutes and often not longer than one minute. With our patients, the best routine has seemed to be one in which five minutes of heat and two minutes of cold or four minutes of heat and one minute of cold were employed. One should always start and end with immersion in hot water to obtain the best vascular response. If the five minute hot, two minute cold routine is employed, from five to seven alternations should be made, thus: 5-2-5-2-5 or 5-2-5-2-5-2-5. It will be seen that such applications would last either nineteen or twenty-six minutes. If the four minute hot, one minute cold routine is employed, the series of alternations should be either seven or nine, thus: 4-1-4-1-4-1-4 or 4-1-4-1-4-1-4-1-4. It will be seen that such an application would last a total of nineteen or twenty-four minutes.

Hench⁹ has employed contrast baths frequently for hypertrophic and atrophic arthritis for many years. Holbrook and Hill¹⁰ have mentioned that they were "especially useful," and Fox and Van Breemen¹ have advocated their employment.

MASSAGE, MANIPULATION AND SPLINTAGE

Massage.—Massage will be found to be of great usefulness, particularly in the treatment of atrophic arthritis.¹¹ It should not be employed, however, if there is acute pain on movement or if there is a marked rise

of temperature in the region of the affected joint. As a rule, direct massage over the joint is to be avoided, although extremely light stroking may at times be employed to relieve pain. As the inflammation subsides, the intensity of stroking and kneading of the muscles and soft tissue around the joint may be increased gradually in an attempt to improve the circulation and tone of the muscles. It is undoubtedly true that harm may result from improper application of massage. Nevertheless it has been found that when, for economic or other reasons, a trained masseuse is not available in the patient's home, a skilled technician can instruct a member of the family in a few harmless simple massage strokes, which may be used either in lieu of or to augment professional treatments. It is a good plan to instruct a member of the patient's family in a simple massage routine which may be employed at home daily and to recommend in addition, if it is obtain-

Fig. 6.—Contrast baths to lower extremities (from Krusen²¹).

able, professional massage two or three times weekly. It is realized that such a plan may be criticized; however, skilled masseuses are unfortunately not universally available and in many instances the patient must be advised to follow the best possible home treatment routine. I am convinced from long experience that when patients are properly instructed concerning home massage much more good than harm will result even though the amateur masseuse cannot hope to approach the skill of the trained technician.

Pemberton and Osgood⁴ pointed out that the process of massage for the patient with arthritis consists essentially of a light form of stroking known as effleurage, which is usually applied in a centripetal direction. As the massage becomes better tolerated, it should progress to a heavier and deeper rubbing and kneading known as petrissage. This kneading should be applied to the accessible tissues around involved joints. The aim of the procedure is to increase the flow of blood, improve the tone of muscles and overcome limitation of motion

in the joint. Poynton and Schlesinger¹² believed that the value of massage was often underrated and that "many crippled rheumatic patients find that, combined with heat, they obtain more relief from it than from any other form of treatment."

Manipulation.—Because every effort should be made to prevent the occurrence of contractures, especially in atrophic arthritis, attempts at mobilization are an essential part of the treatment. Mennell¹³ has said that mobilization should be restored, if possible, at the earliest moment. If one joint is maintained in a state of rigidity there may be lack of mobility in neighboring joints. Careful administration of relaxed movements usually employed immediately following applications of heat and massage will be of great value in the prevention of stiffness of affected joints. Joints which are sensitive should be mobilized after the other joints have had their exercise. Manipulation, even in the form of relaxed movement, should not be employed as long

against subjecting a joint which shows atrophic changes to manipulation. He felt that this warning rested on grounds which could be disputed. He believed that an inflammatory reaction which was sufficient to produce changes in joints must also entail inflammation of peri-articular structures and thought that it followed of necessity that there were possible adhesions in the soft tissues following the subsidence of the inflammation. He said that if these adhesions in the periarticular structures could be freed great benefit might ensue. Copeman² wrote that the physician might find cautious manipulation to be "a powerful weapon in his encounters with many cases of quiescent arthritis" after the inflammatory processes had subsided.

In my opinion there is one type of manipulative procedure which should be employed more frequently, especially in cases of quiescent atrophic arthritis. This procedure can be spoken of as "active assistive" movement of the joint. No anesthetic is employed, but heat followed by gentle massage of the periarticular structures to produce a maximal amount of relaxation should first be applied. The patient then makes an active effort to move the joint through its full range of motion slowly and rhythmically and is assisted by the operator in extending the movement beyond the voluntary range; hence the term "active assistive" movement. Slowly and carefully applied only once or twice a day, it may cause marked increase in range of motion.

Forcible manipulation under anesthesia should never be attempted until this more conservative daily routine has been tried for a period of two or three weeks. Forced manipulation of an arthritic joint should never be considered to be a procedure for home use. Henderson¹⁵ has wisely emphasized the dangers of such forced manipulation, which must always be done with the patient anesthetized. He stated that one of the last things that he would put in the hands of the younger orthopedist is manipulation under anesthesia. He thought that it required more experience than any other procedure. Fractures and dislocations occur too often following inept manipulation for it to be considered lightly as a home or even an office procedure. It must always be remembered that extraordinary caution should be used in any manipulation of an arthritic joint even when the procedure is performed as a hospital measure in the hands of a skilled orthopedist.

It should be pointed out that the shoulder joint and the hip joint, particularly in arthritis, often respond with increased motion following manipulation. On the other hand, there is seldom a good functional result from manipulation of a finger, wrist or elbow. The function of the knees can frequently be improved, but before subjecting a patient to manipulations of the knees one should be certain that the feet are capable of bearing weight and that the hips are not ankylosed or flexed so that the patient cannot walk anyway.

Splints.—Above all else, careful attention should be given to the prevention of deformities, especially in atrophic arthritis. With a little care, prevention of deformity is frequently possible. With neglect, marked deformity is frequent. Once deformities have developed, it may take years to correct them. Splints are an important aid in preventing contractures. Hench³ has pointed out that prevention of deformities is "primarily the responsibility of the general practitioner." It is

Fig. 7.—Shoes: a, a suitable metatarsal bar to relieve pressure on the anterior arch of the foot and a slight lift on the inner side of the sole which proved satisfactory for one patient; b, a soft felt pad within the shoe for the support of the longitudinal arch.

as there is any acute pain on movement. Joints which are mildly sensitive, however, may be mobilized gently, attempts being made to carry them slowly and rhythmically, only once or twice daily, through the fullest possible range in each direction. Above all, the joint should never be jerked or pulled violently, but slow, graduated pressure should be applied up to a point just short of producing severe pain. If there is an increase in joint pain following such relaxed movement which persists until the following day, it will be known that the manipulation has been too rigorous and although application of heat and massage may be continued, further relaxed motion should be discontinued for one or two days and then be applied less strenuously. Mennell¹⁴ has pointed out that warning is often given by physicians

probably the most essential phase of home treatment. The chief deformities to be sought for and prevented are adducted shoulders, thoracic kyphosis and fixation of the thorax, flexion of the elbows and especially of the wrists and knees as well as loss of abduction of the hips and foot drop. The patient should lie on a bed that does not sag. Several times during the day he must lie without pillows and with all joints fully extended. Posterior plaster shells or splints may be essential to prevent or overcome flexion contractures. Night splints which hold an extremity in extension often prevent potential flexion deformities. Particular pains should be taken to avoid the constant use of pillows beneath the knees and under the head, since these frequently induce deformities. The placing of a small pillow under the thoracic part of the spinal column, with the patient lying with the elbows flattened back on the bed with the hands clasped behind the head, will tend to prevent flexion deformity of the spinal column as well as adduction and internal rotation of the shoulder. Padded cock-up splints with the wrist in dorsiflexion frequently may be used to prevent palmar flexion and wrist drop. The use of sand bags, right angle splints or pillows to prevent toe drop and to keep the foot in slight pronation is very important.

SHOES, BANDAGES AND ELASTIC SUPPORTS

Shoes.—The patient who has arthritis may habitually walk around the home for hours at a time in shapeless and loose bedroom slippers because he believes that the slippers "are more comfortable" than shoes. As a matter of fact, a well fitting, stiff shanked shoe is much more comfortable; and in many instances if a soft pad is placed under the instep to support the longitudinal arch of the foot and a metatarsal bar (a raised leather piece on the external sole just back of the anterior arch of the foot) is employed to support the anterior arch, and if occasionally a soft heel pad or wedge is placed under the heel, even the arthritic patient with painful joints may walk with considerable comfort. Ober¹⁶ has pointed out that there is really no such thing as an "orthopedic shoe." The shoeing of each patient is an individual problem. In my experience the employment of soft felt pads and the metatarsal bar is often of value in conjunction with any well fitting and properly constructed shoe (fig. 7).

Hench and Meyerding¹⁷ found that rigid metal supports are usually irritating and at times seem to favor pressure atrophy of the plantar muscles.

Supports.—Occasionally a well fitting elastic knee support or an elastic web bandage applied properly may give comfort, particularly if there is a slight tendency toward a flexion deformity. Such supports may occasionally be applied to the ankles but are rarely of value for other joints.

EXERCISE, POSTURAL TRAINING AND REST

Exercise.—The usual scheme in mobilizing a joint which has been the seat of acute inflammation in arthritis is first to employ relaxed movements; second, active assistive exercises, and at the earliest possible moment to change to active voluntary exercises. In the beginning these active exercises should always be practiced without weight bearing. Weight bearing should

be begun only when sufficient range of motion has been obtained to permit sufficient extension and flexion for reasonably good function and when the muscles have resumed reasonably normal contour and are of sufficient tone to maintain the weight of the body. If active motion is started too soon, pain and muscular spasm will at once develop and serve as a warning to diminish activity.

As soon as the patient starts wary movements of the joints when the acute inflammation begins to subside, this is the signal for the institution of the first cautious massage and gentle relaxed motion. It should be the rule to avoid exercise which, "whether it produces pain or not, is followed by a hang-over such as an increase of pain that day or the next."¹⁷ It is believed that the alternate contraction and relaxation of groups of muscles and their antagonists aids in improving circulation and that the movement of the joint assists in the maintenance of normal physiologic activity.¹⁸ The chief aim in the treatment of chronic atrophic or hypertrophic arthritis should be to restore normal motion of the joints.

Fig. 8.—Specifications for the construction of a homemade "walker." These specifications have been prepared by the Council on Physical Therapy of the American Medical Association.

This is, of course, best accomplished by means of graduated exercises. Most patients with atrophic arthritis are at their worst following periods of inactivity, and most of them find that they can delay disability by resorting to exercise. Active exercise should be entered on at the earliest possible moment. It has been said¹ that the morning toilet of the arthritic patient should include the movement of all his joints. It should be stressed that all such exercises should be slow and through the fullest possible painless range. Jerking motions or "pump handle" movements should be strictly avoided. One slow movement through full range is preferable to many "wiggles" through partial range. Weight bearing should be avoided until it can be well tolerated. Knees should be well straightened before walking is permitted. Walking should usually be started in a "walker," which consists of a frame on wheels which supports most of the patient's weight on the axilla and elbows (fig. 8). Finally the walker is discarded for suitably measured crutches, and at last the objective of unsupported walking may be attained.

Postural Exercises.—An important point in the management of the patient with chronic arthritis is to remove mechanical handicaps by maintaining the best possible alinement of joints. Postural exercises may be valuable for this purpose. It has been noted by Goldthwait and his co-workers¹⁹ that postural exercises not only improve the alinement of joints but also, they believed, tended to improve function of the heart, lungs and abdominal organs. They noted that hypertrophic arthritis affected chiefly points of chronic strain such as the spinal column, fingers, knees and hips. These joints, with the exception of the fingers, are all involved in weight bearing and may be injured by faulty weight bearing. The fingers, because of their great activity, are subject to more trauma than most other joints. It is concluded that proper postural training will tend to lessen trauma by improving alinement of joints. All patients who have arthritis and who show

Fig. 9.—Specifications for the construction of a homemade Hubbard tank, made of heavy galvanized iron, finished in white enamel inside and out. The supports are of 1 inch angle iron. There is a 1½ inch drain with stopper.

any signs of faulty general posture should be taught the five cardinal rules for the assumption of correct posture: 1. Walk with the weight evenly distributed and the feet pointed straight ahead. 2. Roll the hips under. (Contract the buttocks down and the abdominal muscles up, thereby tilting the pelvis back and straightening the lumbar spine. This must be explained and demonstrated to the patient.) 3. Raise the chest up, thereby enlarging the thoracic cavity and raising the diaphragm. 4. Stretch the back part of the top of the head toward the ceiling, thereby straightening the cervical and dorsal spine. 5. Sit, stand and walk as "tall" as possible.

Underwater Exercises.—Occasionally, underwater exercises may be of considerable value in the reestablishment of function for patients with atrophic arthritis. Such exercises are particularly useful when many joints are involved. It is best to administer them in a Hubbard

tank and occasionally these tanks are constructed for home use (fig. 9). In their absence the patient can perform some of the exercises in his own bath tub or in a community swimming pool. Currence²⁰ recommended placing the patient who has arthritis in a bath heated to bodily temperature. The temperature is then gradually increased to a point at which maximal muscular relaxation is obtained. This is usually between 101 and 104 F. (38.3 and 40.0 C.). Thereafter the temperature of the water is gradually lowered to the point of individual comfort, which is usually between 96 and 98 F. (35.5 and 36.6 C.). As soon as complete relaxation is obtained, attempts at active motion are started. At first, gentle stroking massage is employed, then gentle kneading and finally relaxed movements and, later still, active assistive or active movements under water. According to Lowman,²¹ one should avoid protracted periods in the water as well as chilling and too rapid cooling of the skin. Painful joints should be carefully protected while the patient is drying off and changing clothing. Smith²² pointed out that the buoyancy of the water and the constancy of the temperature, which remains at the optimum throughout the entire time of the exercises, are valuable factors in underwater exercise. In addition, there is the possibility of activity in all planes. Joints may be moved through a greater arc of motion without pain than otherwise, and there is a favorable psychologic effect. It has been said that the best way for a patient with arthritis to start walking is in a pool.²³

Occupational Therapy.—The home use of occupational therapy may be extremely useful in rehabilitating patients who have chronic arthritis and many simple devices commonly found in the home may be employed to advantage to strengthen muscles and increase motion in joints by providing certain exercises as part of the occupation. Occasionally a velocipede jig saw and in its absence an ordinary bicycle with the rear wheel jacked up may be used to increase range of motion in the knee, hip joint or ankle. The pedals may be adjusted to increase gradually the limits of motion of the joint. Such pedaling exercises help to develop the muscles of the legs, hips and back. When the ankle alone needs exercise, work with a foot power sewing machine or foot pedal scroll saw may provide the necessary exercise. Clay modeling²⁴ or the use of a plane or hammer may be useful in mobilizing stiffened fingers and wrists. Basket weaving has been recommended for exercising the shoulder, elbow or upper portion of the back. All of these occupations can be followed at home, especially if a skilled occupational therapist can visit the home a few times and start the patient on a proper program of curative occupational procedures; or the patient can be so instructed in an institution before he is sent home.

Rest.—In any case of arthritis, rest is of cardinal importance during the stage of acute inflammation. If there is pain on movement, marked tenderness, fever or increase in the local temperature of the part, rest, as a rule, is indicated. It should be remembered, however,

that such rest should be permitted only with the joint held in a position to prevent contracture and deformity. Furthermore, rest should not be continued indefinitely. As soon as inflammation subsides and the patient starts cautious movement, rest can be discontinued and mobilization started. However, even after inflammation has subsided, joints should be rested in the sense that heavy trauma from weight bearing and other causes should be avoided. Likewise the irritation of repeated movements (wiggling of joints) should be prevented. At the same time that rest is being provided, slow rhythmic movements through the full range of motion in each direction should be attempted once or twice a day. At all times, fatigue should be guarded against. The patient should avoid fatigue rather than remain at absolute rest. The problem is more one of rest plus mobilization than of rest versus exercise. The patient who has chronic arthritis should avoid "hurry and worry" and at the same time should take enough nonfatiguing general exercise to improve his general metabolism and posture and should employ sufficient local exercise to maintain proper mobilization and alignment of his joints. General rest should be prescribed in definite quantity, the prescription being modified from a basic ten hours of rest in bed at night and one hour of rest in bed in the morning and afternoon.

MANAGEMENT OF VARIOUS FORMS OF ARTHRITIS WITH SPECIAL REFERENCE TO PHYSICAL MEASURES

Traumatic Arthritis.—Traumatic arthritis may be divided into two categories (1) extrinsic (exogenous), generally acute and accidental (often occupational or recreational) and (2) intrinsic (endogenous), generally chronic, usually postural or static. In the management of extrinsic, traumatic, intra-articular lesions, which are usually acute, such as arthritis or synovitis, all phases of management, including physical therapy, should be considered by the physician. A typical example of extrinsic traumatic arthritis is "baseball finger." Reassurance, rest, support, the application of radiant heat, contrast baths and light massage which is gradually increased in intensity should be employed. Later, when acute inflammation has subsided, mild exercises of a slow and rhythmic nature, the joint being carried once or twice a day through the fullest possible range, should be employed to restore mobility of the joint. It will be noted that physical measures play an important part in the therapeutic program.

In the management of intrinsic (usually chronic) traumatic intra-articular lesions, either arthritis or synovitis, physical therapy again plays an important part. Such lesions are generally due to repeated minor trauma associated with joint strain, as a result of conditions such as obesity, flatfoot and scoliosis. As with any other form of arthritis, a general plan of treatment should be instituted in which physical therapy is only one phase. In this group, reassurance is needed, rest of the involved joints is indicated, and of particular importance is the elimination of all removable irritating trauma of occupation, recreation, malalignment or obesity. When the so-called microtrauma is caused primarily by obesity, reduction of weight should be instituted. This may be accomplished not only by dietetic management but also by carefully graduated exercises. If the trauma to the joints is due to postural strains, physical exercises are of importance and a routine of

corrective postural exercises should be inaugurated. Likewise, local applications of heat and massage to the involved joints may relieve pain, tenderness and swelling. Corrective shoes and supports are frequently of value. One of the most common forms of intrinsic traumatic arthritis is static arthritis of the knee joints, usually seen in obese, middle aged women who are on their feet much of the time performing their household duties. The application of elastic bandages to the knees in conjunction with the other measures mentioned may be helpful in such cases.

Under the heading of traumatic arthritis may be listed various extra-articular lesions such as traumatic fibrositis, traumatic bursitis and tendonitis. A typical example is "housemaids' knee." For patients having such extra-articular lesions, as usual, a routine of management should be thought out by the physician. In such cases rest, elimination of causative trauma, if possible, and the use of supports such as roller bandages or braces and particularly applications of heat and sedative massage and in fibrositis firm massage may be of value. Heat may be applied in the form of diathermy or radiant heat and should be followed by massage. During the later stages of recovery, mild exercises are indicated.

Specific Infectious Arthritis.—Specific infectious intra-articular lesions, arthritis or synovitis are generally acute but may be chronic. Under this heading may be listed inflammations of joints which are of known infectious etiology, such as gonorrheal arthritis, tuberculous arthritis and syphilitic arthritis. As with other forms of arthritis, the usual general program of treatment should be outlined and all the measures previously mentioned should be considered. During the acute stage of gonorrheal arthritis when the administration of unfortified sulfanilamide therapy is ineffective, a combination of sulfanilamide and fever therapy is definitely indicated. It has been our experience at the Mayo Clinic that about 85 to 90 per cent of patients who have gonorrhea have shown a response to adequate sulfanilamide therapy when it has been properly administered. In cases of gonorrheal arthritis which do respond to chemotherapy, other routine treatment, however, is indicated and physical measures such as the local application of heat, sedative massage and, during the later stages, active assistive exercises may be of great value in overcoming pain, swelling and periarticular adhesions with limitation of joint motion. Exercise is not inaugurated until acute inflammation has subsided. Whirlpool baths, contrast baths, diathermy or radiant heat may be used to advantage as thermal agents for the treatment of such joints. The sedative massage and active assistive exercises will tend to restore some measure of motion in joints which have not been too badly damaged, and rehabilitation will be much more rapidly accomplished by the employment of these physical measures.

Of particular importance from a physical therapeutic standpoint are the dramatic results which can be obtained when a combination of sulfanilamide and prolonged high, artificial fever is used in the treatment of resistant gonorrhea which fails to respond to unfortified chemotherapy. Such a procedure is strictly an institutional one and cannot be considered under the category of home treatment; but the family physician should be familiar with the possibilities of fever therapy in gonorrheal arthritis in order that he may suggest the proper routine in very resistant cases. We have observed in our fever therapy department fifty-three patients having very resistant gonorrhea who failed to respond to appar-

ently adequate sulfanilamide or sulfapyridine therapy. To each of these patients, sufficient sulfanilamide was given orally to raise the hemal concentration of sulfanilamide to more than 9 mg. per hundred cubic centimeters. Thereafter a single session of artificial fever therapy was administered, the patient's bodily temperature being raised to approximately 106.8 F. (41.5 C.) for ten hours. Of these fifty-three patients, all but two had negative cultures following treatment and the majority of patients required only one long session. A few required two or even three sessions. The procedure is difficult and should be employed only by trained technicians working under constant direct medical supervision. A physician should remain with the patient from the beginning to the end of the session. Fever therapy remains the most potent weapon available for the treatment of gonorrhea and, when employed early, improvement in the lesions of the joints may be very spectacular. Fever therapy, nevertheless, is not recommended until other measures have been tried and have failed. However, one should not delay fever therapy for too long a time.

Physical measures likewise play an important part in the treatment of tuberculous arthritis. Heliotherapy, judiciously employed, may be of value. Gradual exposures to the sun, according to the method of Rollier, or routine general irradiations with a quartz lamp are recommended in such cases. As for other types of arthritis, a routine program of treatment should be instituted.

In treating patients who have syphilitic arthritis, artificial fever induced by physical means may be used to advantage. In such cases, repeated fevers are usually administered twice weekly, the bodily temperature being elevated to 105 F. (40.5 C.) for five hours at each session. This also is an institutional procedure and should never be carried out in an office or in a home.

Recently it has been found that undulant fever (brucellosis) responds frequently to fever therapy, and Prickman²⁵ has pointed out that these studies suggest that "this type of therapy be tried in cases of chronic lesions of the bone with or without sinuses from which organisms of the *Brucella* strain can be cultured. . . ." This suggestion offers new possibilities in the treatment of a type of joint lesion which has previously been considered highly resistant to all forms of therapy. A favorable response has been noted in one such patient who, in more than a year, has had no recurrence of a spinal lesion. It is too early to make any positive statement concerning the value of the procedure, but its consideration is recommended in the absence of any other acceptable treatment.

Physical measures may also be used to advantage at times in the treatment of various forms of specific infectious fibrositis and bursitis.

"Nonspecific" Infectious Arthritis. — This group includes the greatest number of conditions commonly treated as arthritis. The etiology is really unknown; hence the use of the term "infectious" may be questioned, although many believe that this type of arthritis is possibly related to streptococcal infections or to their toxins. Under this classification occur various intra-articular lesions such as those which are associated with rheumatic fever, specific ulcerative colitis, scarlet fever and certain diseases of the skin such as psoriasis and

erythema nodosum. Recently fever therapy has been used much more frequently in the treatment of rheumatic fever, and it has been found that routine applications of heat, massage and graduated exercise are valuable as an adjunct in the treatment of arthritis associated with ulcerative colitis. In treating patients who have psoriatic arthritis, the special form of arthritis occasionally seen in association with psoriasis, physical measures have proved to be a valuable adjunct. The associated psoriasis may be treated to considerable advantage by means of a combination of local applications of crude coal tar ointment and ultraviolet radiation as described by Goeckerman.²⁶ Frequently, with an improvement of the cutaneous lesions, the joint manifestations subside. Local applications of heat and massage are also indicated in the treatment of psoriatic arthritis. Roentgen therapy may also prove efficacious in treatment.

Chronic Infectious (Atrophic or Rheumatoid) Arthritis. — Chronic infectious arthritis is really a subdivision of the nonspecific infectious arthritis group; however, because of the prevalence of the former it is given a separate heading. Synonyms for this disease are atrophic, rheumatoid, proliferative, nonspecific, infectious or infective arthritis. It is in this major group of joint conditions that various forms of physical treatment may prove of great auxiliary value. It is well known that there is no specific therapy for this form of arthritis. In treating patients who have chronic infectious (atrophic) arthritis it is essential that a well developed program of treatment be considered. One should never rely on a single therapeutic measure. It is advisable to consider the removal of definitely infected foci, to place the patient on a definite program of rest, general for the body and local for the joints, and to prescribe a carefully organized program of physical treatment. This program should include the employment of thermal agents, massage, manipulation, splints or supports (to prevent or correct deformities), exercises, local for the joints and general postural exercises, as well as occupational therapy. Simple analgesics may be used to advantage, and a general nutritious, eliminative diet may be in order. Psychotherapy in the form of reassurance and special advice to the patient on how to "live with the disease" should be given. Although physical therapy is only one part of such a program, it is a very important phase of treatment.

The extra-articular forms of "nonspecific" arthritis may be grouped into infectious fibrositis and rare forms of myositis. Chronic infectious fibrositis is the most important and the most frequently overlooked form of extra-articular lesion. Slocumb²⁷ has described this condition in careful detail. Under this classification occur such conditions as "capsular rheumatism, peri-arthritis and periarticular fibrositis." There is also a muscular fibrositis which may be localized as in lumbago or torticollis or diffuse as in "generalized muscular rheumatism." There is likewise a bursal fibrositis, as in subacromial bursitis, and a perineural type, as in certain types of sciatica. Lastly there is tendovaginitis; for example, Dupuytren's contracture or tendon ganglion.

Whereas physical therapy is of little use in the treatment of the rare forms of myositis, such as myositis ossificans and myositis fibrosa, physical measures are of extreme value in the treatment of different types of fibrositis. Fibrositis, which is described at great length in the continental literature, is frequently overlooked in this country. It is usually described as consisting of chronic inflammation of white fibrous tissue, and the intramuscular form is said to be characterized particularly by the formation of small palpable nodules or indurations in the subcutaneous tissues or muscles. It has been stated repeatedly by British authors that firm local massage will "break up" many of the indurations with subsequent relief of pain and muscular spasm. The physical treatment consists of local applications of heat followed by extremely heavy local massage over the indurations or nodules. Ordinary massage is of little or no value. It is essential to establish the diagnosis before the heavy massage is applied, because heavy massage is contraindicated in practically all forms of arthritis and is indicated in the treatment only of peri-articular or intramuscular fibrositis. Daily applications of radiant heat followed by very firm massage administered for many weeks will tend to lessen the intensity of exacerbations of the fibrositis and will provide much comfort to the patient suffering from this condition, although such treatment rarely will effect a complete cure.

Degenerative (Senescent or Hypertrophic) Arthritis.—The intra-articular form of degenerative (senescent or hypertrophic) arthritis is the second most frequently encountered type. Synonyms are degenerative osteoarthritis and spondylitis osteo-arthritis. Heberden's node of the finger is included in this classification. When affecting the knee, the "static arthritis of obesity" may be placed in this category rather than under traumatic arthritis, and "menopausal arthritis" may also be included in this classification. The "hypertrophic spinal column of the elderly" and, in the hips, the morbus coxae senilis are also in this classification. Physical treatment plays an important part in the management of these various forms of senescent or hypertrophic arthritis.

As is always the case, physical treatment should be fitted into a general treatment program. This program may be as follows: 1. Reassurance should be given above all else. Whereas reassurance is required in the treatment of most forms of arthritis, it is particularly important in the management of this form. The condition is essentially not as a rule an ankylosing, severely progressive or crippling disease, as may be the case with chronic infectious (atrophic) arthritis. Although hypertrophic arthritis occasionally may be very crippling, usually it is a nuisance, not a calamity. Since every individual with arthritis pictures to himself a friend who has marked deforming arthritis, it is essential that he be informed that the type of arthritis from which he suffers does not, as a rule, result in such deformities. 2. All removable irritating trauma of occupation, recreation or obesity should be eliminated. 3. Physical therapy should be employed in the form of local applications of heat or contrast baths and sedative massage; mild exercises should be used. Wiggling of the joints should be avoided and extensive exercise is not usually required. 4. Occasionally, roentgen therapy may prove beneficial. 5. The patient should be given a well balanced anticonstipation diet or,

if obese, a weight reducing diet may be in order. 6. Supports including corsets for the spinal column and a cane or roller bandages for the knees are often useful. 7. Occasionally, removal of obviously infected foci should be done without promise to the patient of a good result. 8. Vaccines are of debatable value and some outstanding authors believe them to be contraindicated in this condition.

In the management of senescent (hypertrophic) arthritis, physical measures are modified considerably from those used for infectious (atrophic) arthritis. Local thermal applications, particularly contrast baths, may be useful. Mild systemic heating in a tub bath or pack may be somewhat beneficial, but it should be used with caution because this form of arthritis usually occurs in the aged. Careful massage will tend to overcome the moderate stiffness of joints which characterizes hypertrophic arthritis, and the milder exercises will usually be sufficient to maintain mobility of the joints.

"Chemical Arthritis."—In treating patients who have chemical (metabolic or endocrine) arthritis, which includes such conditions as gouty arthritis and hemophilic arthritis, physical measures are of little value with the exception that they may occasionally be employed in the form of heat, sedative massage and mild exercises to produce symptomatic relief from pain and stiffness.

Neoplastic Arthritis.—In treating the patient who has a neoplastic lesion of a joint such as chondromatosis or metastatic tumors such as carcinoma or sarcoma, the only physical agent that is of any great value is the roentgen ray.

Miscellaneous Forms of Arthritis.—Under this classification may be placed the various "mixed types" of arthritis as well as the functional forms of arthritis such as the "hysterical" joint or the myalgia of fatigue and exhaustion. Physical measures, particularly the more spectacular ones, may prove of great value in conjunction with proper psychotherapy in the treatment of the so-called hysterical joint. With proper suggestion, any tangible form of treatment may provide the necessary means of effecting a cure of the hysteria. In myalgia of fatigue, applications of heat followed by massage will remove products of fatigue and hasten the restoration of function.

CONCLUSIONS

The various forms of physical therapy play an extremely important part in the modern treatment of diverse types of arthritis. Most of these physical measures can, with a little ingenuity, be applied in the patient's own home. It is essential that the physician who employs such physical measures should have in mind a workable classification of the arthritides, that the diagnosis be properly established and classified and that a carefully thought out general program of treatment be outlined. Physical treatment is only one phase of the general program, but it is perhaps the most important phase. The various forms of physical treatment should be applied only as indicated for the particular type of arthritis encountered. More extensive employment of the simpler forms of physical therapy by medical practitioners in general should unquestionably be of great benefit to the many unfortunate sufferers from this protean and ubiquitous disease.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, AUGUST 24, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

PLASMA PROTEINS

The role assumed by the proteins of the plasma in physicochemical relationships and in immunologic phenomena of the blood has brought to these constituents more attention than has been given most of the other proteins of the body. Yet the vast amount of experimental work has not provided a clear picture of their formation and fate in the organism. Research work of the past few years has greatly elucidated some aspects of the problem and has afforded at least a working hypothesis with respect to other more obscure phases of the subject. A recent review by Madden and Whipple¹ clearly reflects the present status of our knowledge bearing on the source, production and utilization of plasma proteins.

Although there is evidence that the albumin, globulin and fibrinogen factors of plasma are not as sharply defined as was once supposed (indeed, it seems probable

that they all form part of a single loosely bound protein system) it is practical to consider these fractions individually as they do possess a certain independent importance in biologic reactions. With regard to the site of origin of the proteins of the plasma, the Rochester investigators are convinced that the liver is of primary importance. The production of fibrinogen seems to be definitely dependent on liver function. Damage to the liver is accompanied by a fall in the fibrinogen content of the blood, and regeneration and repair of the liver result in a return of the blood fibrinogen to its normal level.² However, the question of the site of origin of the albumin and globulin of the plasma is more perplexing; almost all the organs of the body have been implicated in this connection. Both clinical and experimental evidence point to the liver as the site of albumin and globulin formation,³ although apparently at least some of the globulin may be formed in cells elsewhere in the body.⁴

While the body has the power of synthesizing proteins, it must be supplied with the proper building material. Hypoproteinemia and edema due to malnutrition illustrate the ultimate dependence of the plasma proteins, like other similar compounds in the body, on exogenous sources. Experimental investigations with animals indicate, moreover, that not only the quantity but also the quality of food protein is of significance in the regeneration of plasma proteins. Although the products of hydrolysis of food proteins normally enter the blood after absorption from the intestine, it is noteworthy that the parenteral administration of protein hydrolysates has been investigated.⁵ The possible practical value of the intravenous administration of the nitrogen required by the body over short periods, including that for plasma protein formation, has been indicated,⁶ and further study of this problem is certainly warranted.

Ample evidence supports the belief that there is a reserve store of building material for plasma protein in the body. That the protein of blood plasma is regenerated even during a fasting period after acute depletion by bleeding was first observed early this century by Morawitz. Since that time other investigators, particularly Whipple and his associates,⁶ have extensively studied the regeneration of plasma proteins in dogs subjected to plasmapheresis, a procedure involving bloodletting accompanied by the reinjection of blood corpuscles suspended in a modified Locke's solution. Apparently the plasma protein reserves are a part of the general body stores, since they may be depleted

by a low protein diet and by fasting. The question of protein storage is, of course, more complex than that of fat or carbohydrate storage, for while fat depots and glycogen may be readily recognized as storage materials it is questionable whether "stored protein" exists as a physically demonstrable entity comparable to fat or carbohydrate stores. Nevertheless, as pointed out by Madden and Whipple, there is protein which may be given up by one organ or tissue under certain conditions without interfering with functions of the organ or of the body. In the light of present evidence it would seem, moreover, that plasma protein does not remain static after being elaborated but rather participates in a dynamic equilibrium with the reserve protein of the body, as suggested by Madden and Whipple. The plasma proteins are thus only a part of a balanced system wherein a steady "ebb and flow" exists between them and other proteins of the body.

THE SUPERIOR PULMONARY SULCUS TUMOR OF PANCOAST

Pancoast¹ reported in 1924 three cases of what seemed to be a new entity among intrathoracic tumors. The neoplasms occurred at a definite location at the thoracic inlet, were characterized by pain around the shoulder and down the arm, Horner's syndrome and atrophy of the muscles of the hand, roentgenologic evidences of a homogeneous shadow at the apex, always more or less local rib destruction and often vertebral infiltration. The name "superior pulmonary sulcus tumor" has been given to this new growth because the term implies its approximate location and the "lack of origin from the lung, pleura, ribs or mediastinum." Pancoast² was able to add four more cases in 1932. A biopsy in one of these cases revealed an epithelioid carcinoma. Pancoast advanced the hypothesis that the tumor had its origin from an embryonic remnant of the fifth branchial pouch.

This concept of a new specific clinical and pathologic entity created controversy. The majority of the observers pointed out that the syndrome described by Pancoast could be initiated by a great variety of conditions in the upper thoracic aperture. Other observers, while impressed with the specificity of the syndrome, argued that scientific proof of the branchial origin of the tumor was not furnished. Browder and De Veer³ were particularly emphatic in denying the specificity of both the syndrome and the tumor and challenged the propriety of the term "superior pulmonary sulcus." They reported five cases which illustrate symptoms of malignant tumor located in the region of the pulmonary apex and upper mediastinum. Postmortem studies demonstrated

that three of the cases were primary carcinomas of the lung, one a metastatic hypernephroma and one a tumor of the thymus. Tobias reported five apical tumors in patients with the symptoms described by Pancoast. Four of these cases were primary carcinomas of the apex of the lung and the fifth a metastatic tumor from carcinoma of the stomach. Other observers recognized the existence of an apical tumor possessing characteristics which set it apart from the tumors commonly occurring in this region but were skeptical of the branchial origin of such tumors. Thus Jacox⁴ reported a case which fulfilled all the criteria of the entity described as superior pulmonary sulcus tumor but which presented the appearance on microscopic study of a mucin-secreting adenocarcinoma suggesting bronchogenic origin. Jacox advanced the view that superior pulmonary sulcus tumor is an atypical form of primary bronchogenic carcinoma. Steiner and Byron⁵ reported three cases of primary apical lung carcinoma with symptoms closely resembling those described by Pancoast.

In a recent contribution Morris and Harken⁶ present an analytic review of the literature on the subject and eight personal cases. They conclude that the Pancoast tumor is a specific entity. They point out that, while the Pancoast syndrome is not specific per se and can be initiated by a variety of conditions, the Pancoast tumor is a definite pathologic entity: it is a specific malignant neoplasm with a histologic picture of epidermoid carcinoma, and it is characterized grossly by its "lack of origin from lung, pleura, ribs or mediastinum." They insist, however, on certain criteria before accepting the tumor as a superior pulmonary sulcus tumor: (1) clinical evidence of an apical tumor expressed in terms of pressure destruction effects on adjacent nerve and osseous tissues (Hare's syndrome), (2) histologic evidence of epithelioma and (3) pathologic evidence based on postmortem studies which are competent to prove (a) the extrapulmonary character of the tumor, (b) its lack of origin from lung, pleura, ribs or mediastinum and (c) its primary nature as determined by exclusion of all possible sources of metastatic origin. According to these authors four cases reported in the literature answer these demands. These cases are one by Clark,⁷ two by Fried⁸ and one by Graef and Steinberg.⁹ These, with their own three cases, make a total of only seven authentic cases thus far reported. In a recent article two Russian clinicians, Melnikov and Derman,¹⁰ likewise point out

the necessity of differentiating between the Pancoast syndrome and the Pancoast tumor. They report three cases, one of which, with a careful postmortem study, answers all the criteria set forth by Morris and Harken.

Certain clinical features about the Pancoast syndrome may be emphasized as characteristic. These are the onset with excruciating pain about the shoulder and the apex of the axilla, the constant and early development of the Horner syndrome, and the constant invasion of the first, second and third ribs and of the vertebrae. The tumor appears to be particularly malignant and refractive to radiation. The surgical removal of such tumors, particularly when well advanced, is difficult, if not impossible. Pain is best controlled by a cervical chordotomy or section of the sensory roots.

Current Comment

MEDICAL LITERATURE AND THE BLOCKADE

Gradually since the end of May there has been a diminution in the receipt of medical publications coming from abroad to the *Quarterly Cumulative Index Medicus* and to the Library of the American Medical Association. The Library has been receiving in the past about 1,400 different periodicals. The most recent shipment from Germany arrived on July 22, at which time, however, only two periodicals were received. On June 26 eight periodicals came, but the last large shipment arrived on May 27. Already, therefore, some of the German publications are more than three months in arrears. Some Austrian weekly publications which used to arrive every seven to ten days have not been received since early in June. Polish and Czechoslovakian journals have not been received for many months. Sixteen such publications have been dropped from the *Index* since the beginning of 1940. Within the last two months official notification has been received of the suspension of eleven French medical periodicals. From Italy the last weekly receipts were at the end of June and few Italian publications have come since that date. The publications from Great Britain for June and July are being received with perhaps a very slight delay. Some publications dated July 1940 arrived in Chicago as late as August 17. The effects of the difficulty in the receipt of foreign periodicals are reflected in the current medical literature department of THE JOURNAL, from which no doubt readers have noticed the absence of some of the foreign publications which used to be listed and abstracted regularly. The *Quarterly Cumulative Index Medicus* will likewise show some diminution in size in the next issue. In the issue for January to March 1940, 8,160 articles were indexed from the foreign literature. In the issue for April to June 1940, 7,590 articles were indexed—a decline of 570 articles. The period July to September will be closed shortly; up to August 19, however, only 3,415 articles have been listed—a decline of more than 50 per cent in the material available. No doubt some of the decline in the foreign medical literature is due to

difficulties concerned with the securing of paper and printing supplies and with the fact that many men are engaged in military activities. Unquestionably also the blockade on shipping has prevented the transmission to the United States of some of the periodicals that are being published.

ABSENCE OF ACQUIRED TETANUS IMMUNITY IN MAN

According to Lahiri¹ of the Immunity Research Laboratory, Calcutta, India, human beings do not acquire a demonstrable immunity against tetanus toxin as a result of environmental exposure. Many individuals acquire specific antitoxins as a result of subclinical infections, as demonstrated with diphtheria,² scarlet fever³ and staphylococcal infections.⁴ In each of these diseases statistical evidence suggests a close correlation between exposure and acquired antitoxic immunity.⁵ A crucial test of the ability of man to acquire a similar immunity against tetanus toxin was attempted by the Calcutta immunologists. Such a test would presumably be afforded by titrations of the antitoxin content of the blood of individuals living in environments known to be highly contaminated with the tetanus bacillus. Lahiri therefore made antitoxin titrations on twenty grooms in constant attendance on horses used in the production of therapeutic antisera and on five laboratory assistants who had handled tetanus toxin and living cultures of *Clostridium tetani* almost daily for several years. The grooms walk barefooted, often with cuts, pricks and abrasions, throughout the yard used by the horses, which yard is known to be highly contaminated with toxigenic strains of the tetanus bacillus. Most of the laboratory workers had had numerous accidental cuts or injuries of the fingers while at work with toxigenic cultures. Blood samples drawn from each of the twenty-five highly exposed individuals were titrated for their tetanus antitoxic content, guinea pigs being used as the experimental animal. All control guinea pigs injected with minimal lethal doses of tetanus toxin developed contractures within twenty-four hours and died between the seventy-second and the eighty-fourth hour. Within the limits of the experimental error, identical results were obtained with parallel injections of toxin incubated with massive doses of the twenty-five human sera. From these negative results Lahiri concludes that there was not a detectable trace of tetanus antitoxin in the blood of any one of his twenty-five highly exposed subjects. From this he concludes that there is no subclinical form of tetanus infection. All of his subjects presumably were frequently infected with living organisms or spores but under conditions not suitable for germination or toxin production. If even minute doses of the toxin had been formed, antitoxins would have resulted.⁶ Clinically, therefore, there is no environmentally acquired immunity to tetanus.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

MILITARY AND NAVAL PERSONNEL

Physicians who are interested in obtaining information regarding opportunities for military or naval service may consult United States army corps area commanders and corps area surgeons, and also medical officers in charge in naval districts:

Present U. S. Army Corps Area Commanders and Corps Area Surgeons

FIRST CORPS AREA.—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut.

Headquarters: Boston Army Base, Boston.

Corps Area Commander: Major Gen. James A. Woodruff.

Corps Area Surgeon: Col. John J. Reddy, M. C.

SECOND CORPS AREA.—New York, New Jersey, Delaware, Puerto Rico.

Headquarters: Governors Island, New York.

Corps Area Commander: Lieut. Gen. Hugh A. Drum.

Corps Area Surgeon: Col. Frank W. Weed, M. C.

THIRD CORPS AREA.—Pennsylvania, Maryland, Virginia, District of Columbia.

Headquarters: U. S. Post Office and Court House, Baltimore.

Corps Area Commander: Major Gen. James K. Parsons.

Corps Area Surgeon: Col. Henry C. Pillsbury, M. C.

FOURTH CORPS AREA.—Alabama, Florida, Georgia, Louisiana, Mississippi, North and South Carolina, Tennessee.

Headquarters: Post Office Building, Atlanta, Ga.

Corps Area Commander: Lieut. Gen. Stanley D. Embick.

Corps Area Surgeon: Col. Chester R. Haig, M. C.

FIFTH CORPS AREA.—Ohio, Kentucky, Indiana, West Virginia.

Headquarters: Fort Hayes, Columbus, Ohio.

Corps Area Commander: Major Gen. Campbell B. Hodges.

Corps Area Surgeon: Col. Will L. Pyles, M. C.

SIXTH CORPS AREA.—Michigan, Wisconsin, Illinois.

Headquarters: Post Office Building, Chicago.

Corps Area Commander: Lieut. Gen. Stanley H. Ford.

Corps Area Surgeon: Col. Paul W. Gibson, M. C.

SEVENTH CORPS AREA.—Missouri, Kansas, Iowa, Nebraska, Minnesota, North and South Dakota, Arkansas.

Headquarters: New Federal Building, Fifteenth and Dodge streets, Omaha.

Corps Area Commander: Major Gen. Percy P. Bishop.

Corps Area Surgeon: Col. Herbert C. Gibner, M. C.

EIGHTH CORPS AREA.—Texas, Oklahoma, Colorado, New Mexico, Arizona.

Headquarters: Fort Sam Houston, San Antonio, Texas.

Corps Area Commander: Major Gen. Herbert J. Brees.

Corps Area Surgeon: Col. W. Lee Hart, M. C.

NINTH CORPS AREA.—Washington, Oregon, Idaho, Montana, Wyoming, Utah, Nevada, California, Alaska.

Headquarters: Presidio of San Francisco.

Corps Area Commander: Lieut. Gen. John L. DeWitt.

Corps Area Surgeon: Col. Condon C. McCornack, M. C.

Colonel Haig is temporarily acting as Surgeon of the Fourth Corps Area. Col. James E. Baylis will replace him in September.

All of these officers are subject to change of station. It is therefore advisable, when addressing communications, simply to address "The Corps Area Commander" or "The Corps Area Surgeon" of the particular corps area concerned, rather than the individual by name.

Naval Districts and Medical Officers in Charge

FIRST NAVAL DISTRICT.—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island.

Headquarters: Boston.

Medical Officer in Charge: Capt. John L. Neilson, M. C.

THIRD NAVAL DISTRICT.—Connecticut, New York, northern part of New Jersey including counties of Mercer and Monmouth, and all counties north thereof.

Headquarters: New York.

Medical Officer in Charge: Capt. Edward C. White, M. C.

FOURTH NAVAL DISTRICT.—Pennsylvania, southern part of New Jersey including Philadelphia, counties of Burlington, Ocean and all counties south thereof; Delaware.

Headquarters: Philadelphia.

Medical Officer in Charge: Capt. John B. Kaufman, M. C.

FIFTH NAVAL DISTRICT.—Maryland, West Virginia, Virginia and the counties of Currituck, Camden, Pasquotauk, Gates, Perquimans, Chowan and Dare in North Carolina.

Headquarters: Naval operating base at Norfolk, Va.

Medical Officer in Charge: Capt. William A. Angwin, M. C.

SIXTH, SEVENTH, AND EIGHTH NAVAL DISTRICTS.—

(Sixth) South Carolina, Georgia, and North Carolina except the counties of Currituck, Camden, Pasquotauk, Gates, Perquimans, Chowan and Dare.

(Seventh) Florida, except counties west of Apalachicola River.

(Eighth) Florida, counties west of Apalachicola River, Alabama, Tennessee, Louisiana, Mississippi, Arkansas, Oklahoma, Texas.

Headquarters: Charleston, S. C.

Medical Officer in Charge: Capt. Thomas W. Raison, M. C.

NINTH NAVAL DISTRICT.—Ohio, Michigan, Kentucky, Indiana, Illinois, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas.

Headquarters: Great Lakes, Ill.

Medical Officer in Charge: Capt. Andrew B. Davidson, M. C.

TENTH NAVAL DISTRICT.—Puerto Rico and Virgin Islands.

Headquarters: San Juan, P. R.

Medical Officer in Charge: Comdr. James G. Dickson, M. C.

ELEVENTH NAVAL DISTRICT.—New Mexico, Arizona, southern part of California, including counties of Santa Barbara, Ventura, Los Angeles, and San Bernardino and all counties south thereof.

Headquarters: San Diego.

Medical Officer in Charge: Capt. David C. Cather, M. C.

TWELFTH NAVAL DISTRICT.—Colorado, Utah, Nevada, northern part of California including counties of San Luis Obispo, Kern, Inyo and all counties north thereof.

Headquarters: San Francisco.

Medical Officer in Charge: Capt. Edward U. Reed, M. C.

THIRTEENTH NAVAL DISTRICT.—Washington, Oregon, Idaho, Montana, Wyoming, Alaska.

Headquarters: Seattle.

Medical Officer in Charge: Capt. Harry A. Garrison, M. C.

FOURTEENTH NAVAL DISTRICT.—Hawaiian Islands and islands to westward including Midway, Kure, Wake, Johnson, Sand Islands and Kingman Reef.

Headquarters: Pearl Harbor, T. H.

Medical Officer in Charge: Capt. Robert E. Stoops, M. C.

FIFTEENTH NAVAL DISTRICT.—Panama Canal Zone.

Headquarters: Canal Zone.

Medical Officer in Charge: Capt. Walter C. Espach, M. C.

SIXTEENTH NAVAL DISTRICT.—Philippine Islands.

Headquarters: Cavite, P. I.

Medical Officer in Charge: Capt. Clyde B. Cameron, M. C.

ORGANIZATION SECTION

OFFICIAL NOTES

THE CLEVELAND SESSION

To Be Held During the First Week in June

The Board of Trustees has selected June 2-6, 1941, as the date for the Ninety-Second Annual Session of the American Medical Association.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—S. J. Res. 286 has passed the Senate and the House with amendments, proposing to authorize the President, during the period ending June 30, 1942, to order into active military service, in the Western Hemisphere and in the territories and possessions of the United States, for a period of one year members and units of the National Guard, Organized Reserve and retired personnel of the Army.

Bills Introduced.—S. 4269, introduced by Senator Wagner, New York, proposes to amend the Social Security Act and the Internal Revenue Code so as to extend old-age and survivor insurance benefits and unemployment benefits to, among

others, employees of nonprofit religious, charitable, scientific, educational and anticruelty organizations, except ordained ministers and members of religious orders performing their duties in such orders and student nurses and interns. H. R. 10334, introduced by Representative Elliott, California, and H. R. 10360, introduced by Representative Murdock, Arizona, propose to authorize the Surgeon General of the United States Public Health Service to allot to the several states and political subdivisions thereof and the District of Columbia federal grants-in-aid to be used for establishing and maintaining adequate measures for the prevention, treatment and control of tuberculosis among migrants, and also for studying, investigating and demonstrating methods of developing more effective measures for accomplishing that purpose, including the training of personnel. Federal funds appropriated each year, not to exceed \$1,000,000 for the fiscal year 1941, are to be allotted on the basis of (1) the migratory population, (2) the extent of the tuberculosis problem among the migratory population, (3) existing facilities for the care of tuberculosis patients and (4) the financial needs of the respective states and other areas. Necessary rules and regulations are to be prescribed by the Surgeon General, with the approval of the Federal Security Administrator and after consultation with a conference of state and territorial health officers.

MEDICAL ECONOMIC ABSTRACTS

UTAH MEDICAL AND HOSPITAL BENEFIT ASSOCIATION

The Utah Medical and Hospital Benefit Association, Inc., was organized by the Utah State Medical Association in cooperation with various hospital administrators and lay persons under the insurance laws of the state of Utah as an assessment benefit association in the early part of 1940. The Utah Medical and Hospital Benefit Association, Inc., is a nonprofit voluntary association and is subject to supervision of the commissioner of insurance of the state of Utah.

The general purpose of the association is to secure for its subscribing members medical service and hospital care and to reimburse the subscribing members for all or a portion of the cost of such medical services and hospital care according to the terms and provisions of the subscriber's contract.

The board of directors is made up of nine members, a majority of whom must be medical doctors in good standing of the Utah State Medical Association. One of the members of the board of directors who is not a member of the Utah State Medical Association must be a member of the Utah State Hospital Association. The president, first vice president and secretary of the association must be medical doctors in good standing of the Utah State Medical Association.

CONTRACTS

The Utah Medical and Hospital Benefit Association, Inc., offers two subscribers' contracts, one for partial medical and surgical reimbursement, and one for limited hospitalization expense reimbursement. It is contemplated that the benefits of the two contracts will provide complete coverage for limited reimbursement of all medical services and hospital care specified in the contracts.

The contract contains a schedule of maximum reimbursements for surgical operations and the treatment of fractures and dislocations. This schedule does not indicate the physician's fees but only the limit of reimbursement by the association to its subscribers.

If the subscriber obtains medical care for the following illnesses the association will reimburse him \$3 per physician's visit up to a maximum of \$50: pneumonia, typhoid, diabetes, not

preexisting, meningitis, coronary occlusion, tularemia and undulant fever. The association will pay \$25 reimbursement for delivery in obstetric cases when both the husband and wife have been members in good standing for one year. When the medical and obstetric cases are not hospitalized, \$5 additional will be allowed for laboratory and x-ray procedure in each case.

LIMITATIONS

No subscriber or dependent may receive more than \$100 of benefits in one year and no family more than \$300 of benefits in one year. If two or more surgical operations are performed for the same accident or illness the association will reimburse the subscriber for the one for which the largest reimbursement is payable. The association will not provide reimbursement for any conditions for which the subscriber is entitled to benefits under workmen's or veterans' compensation laws.

BENEFITS OF THE HOSPITALIZATION EXPENSE CONTRACT

A subscriber or dependent is entitled to \$4 a day for twenty-one days in any one year while he is confined as a bed patient in a hospital recognized by the medical profession as a proper institution for the care of physically disabled persons and under the care of a licensed physician. In addition an amount up to the following maximum will be provided for regularly hospitalized bed patients:

- \$ 5 for ether anesthesia
- 10 for gas anesthesia
- 15 for use of the operating room
- 20 for x-ray services, excluding roentgen therapy
- 5 for special laboratory services

LIMITATIONS

Total benefits to any one subscriber or dependent shall not be more than \$150 a year for a subscriber and one dependent, not more than \$300 for a subscriber and more than one dependent and not more than \$400 in any one family.

Payment for hospitalization for herniotomy, tonsillectomy, adenoidectomy and operations on the nasal septum and sinus is allowed only after contracts have been in effect for one year; for obstetrics, only after husband and wife have been subscribers for one year. Benefits for hospitalization for removal of tonsils or adenoids shall be for one day of twenty-four hours only.

No benefits will be furnished for conditions for which subscribers or dependents are entitled to benefit under any workmen's or veteran's compensation laws, or for pulmonary tuberculosis, acute or chronic alcoholism, acute venereal diseases, mental disorders, quarantinable diseases, drug addiction, self-inflicted injuries or for conditions resulting from unlawful acts, known preexisting deformities, illnesses or abnormalities, for rest cures and for diagnostic purposes.

ENROLMENT

Any person in the state under 65 years of age in good health may apply through a group of not less than ten persons for membership in the Utah Medical and Hospital Benefit Association, Inc. Such a group must have taken the necessary action,

Premiums

	Monthly	Quarterly	Semiannual	Annual
Medical and Surgical Reimbursement Contract				
One person	\$1.00	\$3.00	\$ 6.00	\$10.80
Two persons	1.75	5.25	10.50	18.00
Three or more persons..	2.25	6.75	13.50	24.00
Hospitalization Expense Contract				
One person	1.00	3.00	6.00	10.80
Two persons	1.75	5.25	10.50	18.00
Three or more persons..	2.25	6.75	13.50	24.00

indicating desire to make available subscription to these contracts, and have appointed a remitting agent to handle the collection of premium payments from subscribing members. Such groups to be acceptable must have been organized for some purpose other than the purchase of insurance. They may be church, social, professional, common employer, farm bureau or fraternal in nature. The subscriber may include all dependents under 19 years of age at somewhat lower premium rates. A registration fee of \$1 is required of each member when applying. A subscriber may purchase either the medical and surgical contract or the hospitalization expense contract or both.

ILLINOIS COMMITTEE ON MEDICAL BENEVOLENCE

The House of Delegates of the Illinois State Medical Society at its annual meeting, May 23, voted that certain changes be made in the constitution and by-laws to enable the society to establish a benevolent fund for indigent physicians and their widows. The plan adopted closely resembles the one which has been operating in Pennsylvania for the past thirty-seven years.

The members of the Committee on Medical Benevolence are John S. Nagel, chairman, 185 North Wabash Avenue, Chicago; Charles H. Hulick, Shelbyville, and Clarence H. Boswell, Rockford.

PURPOSES OF THE COMMITTEE

The purposes of the committee are:

1. To create a benevolence fund (a) through allocation of \$1 each year from dues of each member, (b) through gratuities, endowments and so on, and (c) through the efforts of the Women's Auxiliary to the Illinois State Medical Society.
2. To investigate cases of alleged financial difficulties on the part of members, their widows or widowers.
3. When found worthy, to appropriate regular monthly benefits not to exceed from \$25 to \$30 a month in any one case. When deemed advisable, it may appropriate more over a short period of time when rehabilitation seems probable.
4. To designate the component society secretary in each county as the county chairman to submit applications from members for benefits and then to see that a questionnaire form is properly executed to give the desired information relative to the case. The councilor of the district may assist the committee in submitting names of members, or their widows or widowers, when he believes the individual is entitled to the benefits herein prescribed.
5. When it is the opinion of the committee that the case is a worthy one and benefits should be allowed, the chairman of the committee should notify the secretary of the state medical

society, stating the amount agreed on as the regular allowance, stating the intervals at which the benefits shall be paid, so that proper vouchers may be submitted.

THE INVESTIGATIONS

When it is reported to the committee that a member or the widow or widower of a member is needy and unable to secure the necessities of life, a questionnaire form shall be submitted from the secretary's office asking for the following information:

1. A brief social history of the applicant, past and present. Data concerning reasons for being in want whenever possible, and all other pertinent information which will enable the committee to take the proper action.
2. A brief financial history including present assets and income, sources and amount.
3. Disbursing of present resources—(rent, food, clothing, and so on).
4. Statements as to probable permanence of the present distress.
5. Any possible sources of assistance, such as (a) relatives, (b) friends, (c) fraternal organizations, (d) insurance and (e) pensions.
6. Have all sources of help been solicited?
7. Additional information. Means by which influence might be exerted to find employment or some other source of income. Is there a possibility of rehabilitation? (With moderate financial assistance over a short period of time, would it be possible for the applicant to become self supporting?)

PROCEDURE

Requests from members or their widows or widowers for assistance, if submitted to the secretary, shall be referred to the committee promptly. At the same time a questionnaire form will be submitted to the applicant or to the county society secretary, or to the councilor if the information is submitted by him. All possible information which will aid the committee in determining the eligibility for assistance, the amount actually needed or, if rehabilitation through short time payments is probable, should be submitted promptly.

Each case will receive the proper consideration by the entire committee, which shall pass final judgment on (1) eligibility for aid, (2) the amount of aid and (3) whether for a short time or permanently.

The decision of the committee shall be final and there will be no higher authority within the society to whom appeals from decisions of the committee can be referred.

In the event that additional income is received and the individual is no longer eligible for further benefits, the county society secretary or the councilor who submitted the data should notify the committee of these facts promptly.

The Medical Benevolence Fund shall be subject to an annual audit as are other funds of the Illinois State Medical Society, although merely the amount of the fund, the payments made during the year, the additions to the fund and the interest from investments shall be mentioned. Only the income from the fund shall be used to pay benefits. The names of beneficiaries shall not appear in the annual audit nor shall they be mentioned in the annual report of the committee to the house of delegates.

The secretary of the state medical society shall maintain a separate file for all correspondence relative to beneficiaries, amounts paid, investigations and minutes of meetings of the committee, which shall be a closed file and not open to inspection by others than members of the committee, the auditor or a regularly designated committee of the house of delegates.

The council of the Illinois State Medical Society in regular session on Aug. 4, 1940, approved the procedure, and the committee was instructed to make the necessary arrangements to function immediately.

The First Twelve Years.—Human material is easy to shape at birth and through young childhood. It soon begins to set, and by the time puberty is reached the chance of all basic molding is gone. If I can control training until the twelfth year, I am confident of changing radically the behavior patterns and personality of any child.—Holman, Leslie B., *As the Twig is Bent*, New York, Macmillan Company, 1940.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Changes in Health Officers.—Dr. Hollis H. Buckelew, Little Rock, has been assigned as director of the Garland County health unit.—Dr. Kirk T. Mosley has returned as director of the Miller County health unit at Texarkana after completion of his study in public health at Harvard University, Boston.—Dr. Hugh Mobley, formerly of Wilson, has been appointed health officer for White County with offices in Searcy.

Sanatorium Building Program Completed.—The Arkansas Tuberculosis Sanatorium held a dedication, July 4, to mark the completion of a building program that extended over nearly two years and involved an expenditure of about \$2,500,000. Twenty-five new building units were constructed and equipped and repairs and additions were made to all old buildings that are to remain in use. The new buildings include a new hospital with 511 beds; a building for 118 ambulant patients; a "commons" building containing dining rooms and various service units; a nurses' home for 120 persons; two employees' dormitories with a capacity of seventy-two persons each; twelve cottages for physicians and department heads; a barracks for male employees; a power plant, cannery, dairy barn, feed storage barn and a building for guinea pigs. Funds for the building program were provided by the legislature, which in 1938 appropriated \$1,400,000, and by a PWA grant of \$949,071. The original sanatorium was opened in 1910 with accommodations for sixty-four patients, with Dr. John S. Shibley as superintendent. Dr. John Stewart became superintendent on the death of Dr. Shibley and after Dr. Stewart's death in 1930 Dr. Jesse D. Riley, the present head, was appointed. At the formal dedication ceremony Dr. Riley presided; W. A. Doppler, Ph.D., New York, field director of health education of the National Tuberculosis Association, made an address entitled "Don't Fear Tuberculosis; Fight It," and Governor Carl E. Bailey spoke on the growth and value of the sanatorium.

CALIFORNIA

Dr. O. N. Andersen Goes to Stanford.—Dr. Oswald N. Andersen, assistant superintendent of Barnes Hospital, St. Louis, and previously connected with the Council on Medical Education and Hospitals, American Medical Association, Chicago, has been appointed general director of the School of Hygiene and Physical Education at Stanford University, Palo Alto, with the rank of associate professor.

COLORADO

State Medical Meeting at Glenwood Springs.—The seventieth annual session of the Colorado State Medical Society will be held in Glenwood Springs, September 12-14, at the Hotel Colorado. The guest speakers will be:

- Dr. Nathan B. Van Etten, New York, President of the American Medical Association, An American Health Program.
- Dr. Paul B. Magnuson, Chicago, Treatment of Arthritis by Joint Debridement; also The Choice of Method of Treatment of the Neck of the Femur.
- Dr. John H. Talbott, Boston, Clinical Consideration of Gout and Other Arthritides.
- Dr. Arthur E. Hertzler, Halstead, Kan., Wound Healing.
- Dr. Edward L. King, New Orleans, Management of Prolonged Labor; also Hemorrhages in Pregnancy.
- Dr. Tom Douglas Spies, Cincinnati, Vitamin Therapy in Deficiency Diseases.

Dr. Edward H. Skinner, Kansas City, Mo., will be the guest speaker at the annual banquet, Saturday evening, September 14. Among Colorado physicians who will present papers will be:

- Dr. Charles Douglas Deeds, Denver, Recent Advances in the Diagnosis and Treatment of Heart Disease.
- Dr. David W. Boyer, Pueblo, The Use of Local Anesthesia in the Reduction of Fractures.
- Dr. Osgood S. Philpott, Denver, Tropic Ulceration Following Surgical Procedures for the Relief of Trigeminal Neuralgia.
- Dr. Lanning E. Likes, Lamar, New Deal Medicine Man.
- Dr. Leonard Freeman Jr., Denver, Thoracoscopy.
- Col. Robert B. Hill, M. C., U. S. Army, Fitzsimons General Hospital, Denver, Subtotal Gastrectomy.
- Dr. Leo W. Bortree, Colorado Springs, Physical Abnormalities Found in College Students.

ILLINOIS

Personal.—Dr. George A. Wiltrakis, assistant managing officer and medical director of the Chicago State Hospital, has been appointed managing officer of the Alton State Hospital. He succeeds Dr. Felix W. Sokolowski, resigned. Dr. Edward Ross has been acting officer.—Dr. Charles S. Woods, Cleveland, has been appointed general superintendent of the Methodist Hospital, Peoria.—Dr. and Mrs. Stanley R. Walker, Chebanse, were entertained at a banquet, June 2, to celebrate their golden wedding anniversary and Dr. Walker's completion of fifty-one years in medical practice. Dr. Edwin S. Hamilton, Kankakee, was toastmaster.—Dr. Roy S. Bothwell, Batavia, has been elected to emeritus membership in the Illinois State Medical Society, having completed fifty years in the practice of medicine.

Conference on Poliomyelitis.—State district health officers and nurses held a special conference on poliomyelitis recently in Springfield at the call of Dr. Albert C. Baxter, director of the Illinois Department of Public Health. Drs. Sidney O. Levinson and Philip Lewin, Chicago, addressed the meeting. Dr. Levinson discussed treatment, with special emphasis on measures for prevention of crippling. Dr. Lewin described the work of the National Foundation for Infantile Paralysis and also discussed after-care of patients, including methods of splinting and physical therapy. District health officers will be prepared to assist physicians throughout the state in diagnosis and treatment, it was announced. Each district health superintendent will have at his office a supply of convalescent human serum and emergency splints so that prompt treatment may be instituted in the home as soon as the diagnosis is established.

INDIANA

Personal.—Dr. Joseph S. Skobba, a member of the staff of the Central State Hospital, Indianapolis, has been appointed superintendent of the Muscatatuck Colony at Butlerville, effective August 1. Dr. George E. Denny, who has been superintendent since 1937, has resigned because of impaired health and will return to his home in Madison, it is reported.

Changes at Indiana University.—Appointments and promotions at the Indianapolis division of the Indiana University School of Medicine, effective July 1, include:

- Dr. Charles Eli Cottingham, associate in mental and nervous diseases, to be associate emeritus.
- Dr. Alexander T. Ross, Wahjamega, Mich., assistant professor of neurology and psychiatry.
- Drs. Jacob K. Berman, Robert L. Glass, Cleon A. Nafe and John E. Owen, from assistant to associate professors of surgery.
- Dr. William V. Woods, to assistant professor of orthopedic surgery.
- Dr. Harold M. Trusler, to associate professor of surgery.
- Dr. Dennis S. Megenhardt, to associate in plastic surgery.
- Dr. Carl P. Huber, to associate professor of obstetrics.
- Dr. Robert M. Dearmin, to assistant professor of otolaryngology.
- Dr. Bernard J. Larkin, to clinical professor of ophthalmology.
- Dr. Arthur P. Echternacht, to assistant professor of radiology and roentgenologist to university hospitals.

Dr. Alois B. Graham, chairman of the division of gastroenterology and professor of surgery, will become professor emeritus of surgery. Dr. Joseph Warren Ricketts, clinical professor of surgery, will succeed him as chairman of the division.

KENTUCKY

Personal.—Dr. John Walker Moore, dean and professor of medicine, University of Louisville School of Medicine, Louisville, received the honorary degree of doctor of science from Davidson College, Davidson, N. C., recently.

Meeting of Health Officers.—Reuben L. Kahn, Sc.D., director of laboratories, University Hospital, and assistant professor of bacteriology, University of Michigan Medical School, Ann Arbor, and Dr. Vincil Rogers Deakin, assistant professor of clinical genito-urinary surgery, Washington University School of Medicine, St. Louis, were guest speakers at the annual meeting of city and county health officers in Louisville, July 29-31.

Society News.—Hopkins County was host to the second councilor district medical society in Madisonville, June 28, with the following speakers, all of Louisville: Drs. Charles M. Edelen, on "Surgery of Trauma"; Samuel A. Overstreet, "Cancer of the Stomach"; John Keller Mack, "Tuberculosis in Children," and Charles Dwight Townes, who presented a motion picture on ophthalmic surgery. Dr. Austin F. Finley, Madisonville, presented case reports.—Dr. Willis P. McKee, Eminence, addressed the Henry County Medical Society, New Castle, in June on "Gonorrhea in the Male."—The sixth and seventh councilor districts met at Harrodsburg, June 27, with

the following speakers: Drs. George E. Lowrey, Harrodsburg, on "A Short Review of Tularemia"; Frank M. Stites Jr., Louisville, "Proper Evaluation of Gastric Symptoms"; David Y. Keith, Louisville, "Use of Radiation in Skin Neoplasms and Inflammations"; Charles A. Vance, Lexington, "Intestinal Obstruction," and Lee Palmer, Louisville, "Sulfa-pyridine in the Treatment of Pneumonia in Children."

MASSACHUSETTS

Intern's License Limited to Three Years.—The Massachusetts law permits "limited registration" to interns or medical officers of hospitals, entitling them to practice medicine only in the hospital or other institution designated in the special certificate or outside if under proper supervision by registered physicians. This registration has previously been for such time as the board of registration prescribed. On June 27, the Massachusetts Board of Registration in Medicine voted to limit the period for which an intern's license may be issued to three years. It is the opinion of the board that if a physician wishes to practice more than three years in the state he should be registered as a qualified physician, which requires an examination.

Personal.—Dr. Charles Purcell Roberts is now medical director of the health service of Massachusetts Memorial Hospitals, Boston University School of Medicine, under the direction of Dr. Chester S. Keefer, it is reported.—Dr. Elliott P. Joslin, clinical professor of medicine emeritus, Harvard Medical School, Boston, received the honorary degree of doctor of science at the annual commencement of Harvard University, June 20.—Dr. Walter B. Cannon, Boston, received the honorary degree of doctor of laws at the June commencement of Washington University, St. Louis, where he delivered the principal address.—At the annual meeting of the state board of registration in medicine, July 11, Dr. Francis R. Mahony, Lowell, was reelected chairman for the coming year and Dr. Stephen Rushmore, Boston, reelected secretary.—Dr. Rafe Nelson Hatt, Longmeadow, has been appointed a member of the state public health council for a five year term, succeeding Dr. Charles F. Lynch, Springfield, whose term expired.

MICHIGAN

Inspection of Cabin Camps and Resorts.—A sanitary inspection of cabin camps, trailer camps, resorts and other summer recreation centers in Michigan is rapidly being completed, according to the state department of health, August 1. The camps and resorts meeting the sanitary requirements outlined by the state will now be marked by a large black and white roadside sign reading "sanitation approved" in order that the visitors will know where sanitary accommodations are available. The resorts are being classified in three types according to the quality of the sanitary facilities offered: Type 1 includes those having complete modern facilities, including hot and cold running water, flush toilets, electric lights and so on; type 2 may have some of these facilities, but not all, and type 3 will have safe water supplies and sewage disposal systems, but these need not be of the most modern type. All the resorts posted with "sanitation approved" signs will be safe from a health standpoint, it was stated. It is planned to make a directory of approved resorts available to the public.

NEW YORK

Annual Meeting of School Physicians.—Dr. William E. Ayling, Syracuse, was elected president of the New York State Association of School Physicians at the annual conference held at Saratoga Springs, June 24. Drs. Edgar Bieber, Dunkirk, and Clara Adele Brown, Oswego, were elected vice president and secretary, respectively. The speakers included Drs. Elmer H. Ormsby, Amsterdam, on "The Physical Examination of School Personnel"; Lee S. Preston, Oneida, "Laboratory Studies On and Intensive Follow-Up of High School Athletes," and Daniel J. Kelly, Pd.D., superintendent of schools, Binghamton, "Sex Education and the Schools."

Semicentennial of Biological Laboratory.—The Biological Laboratory of the Long Island Biological Association, Cold Spring Harbor, celebrated its semicentennial June 29. Addresses were made by Arthur W. Page, president of the association; Harold C. Urey, Ph.D., professor of chemistry, Columbia University, New York, and Robert Cushman Murphy, D.Sc., New York, of the American Museum of Natural History. Exhibits were shown at the John D. Jones Laboratory, including, among others, electric potentials of the electric eel, the living frog heart and a marine algal cell, and the application of electrophoresis to protection against the allergies.

New York City

Training in Forensic Medicine.—New York University College of Medicine makes available each year to a few physicians an opportunity to secure specialized training in forensic medicine, according to an announcement. The training affords an opportunity to work with the medical examiners of New York and Essex County, N. J., and the chief toxicologist of New York. Those interested in learning more about the work may obtain the information from the office of the dean, 477 First Avenue, New York.

The Ledyard Fellowship for 1941.—Applications for the Lewis Cass Ledyard Jr. Fellowship, which was established in 1939 at the New York Hospital and Cornell University Medical College, should be in the hands of the committee before December 15. The fellowship amounts to about \$4,000, of which \$3,000 will be a stipend and \$1,000 may be used for supplies or expenses of research in medicine and surgery or in any closely related field. Preference will be given to younger applicants who are graduates in medicine and who have demonstrated fitness to carry on original research of high order. Applications should be addressed to The Committee of the Lewis Cass Ledyard Jr. Fellowship, The Society of the New York Hospital, 525 East Sixty-Eighth Street, New York.

Staff Changes at Rockefeller Institute.—The board of scientific directors of the Rockefeller Institute for Medical Research announces promotions and appointments effective on or after July 1. The promotions are:

Associate member to member: Duncan A. MacInnes, Ph.D., Dr. Richard E. Shope and Wendell M. Stanley, Ph.D.

Associate to associate member: Moses Kunitz, Ph.D., and Alfred E. Mirsky, Ph.D.

Assistant to associate: Dr. Douglas A. Macfadyen and William Trager, Ph.D.

Fellow to assistant: Armin C. Braun, Ph.D., Malcolm S. Ferguson, Ph.D., Birdsey Renshaw, Ph.D., and Dr. William C. Spring Jr.

New appointments are as follows:

Assistants: Gail L. Miller, Ph.D., Howard A. Schneider, Ph.D., and Dr. Armine T. Wilson.

Fellows: James A. Baker, Ph.D., Claude A. Knight Jr., B.S., Kermit W. Kreitlow, Ph.D., Margaret R. McDonald, Ph.D., and Dr. Walter Schlesinger.

Faculty Changes—Professor Loewi Comes to New York University.—The council of New York University announces the appointment of Dr. Otto Loewi, for many years director of the faculty of pharmacology at the University of Graz, Austria, and co-winner of the Nobel Prize in medicine and physiology in 1936, as research professor of pharmacology. Dr. Daniel B. Kirby, assistant clinical professor of ophthalmology at Columbia University College of Physicians and Surgeons, has been appointed professor of ophthalmology; Dr. Bernhard Dattner, assistant clinical professor of neurology, and Dr. Howard C. Taylor Jr., associate professor of obstetrics and gynecology. Dr. Edward R. Maloney, professor of dermatology and syphilology and since September 1938 head of the department, has been made professor emeritus and Dugald E. S. Brown, Ph.D., assistant professor of physiology, resigned to become professor of physiology at the New York University College of Dentistry. In addition, the following promotions were announced:

Dr. Samuel Brock, to be professor of neurology.
Dr. Samuel Bernard Wortis, associate professor of neurology.
Dr. Harry Bakwin, associate professor of pediatrics.
Dr. Walter H. McNeill Jr., associate professor of urology.
Dr. Leo Spiegel, clinical professor of dermatology and syphilology.
Dr. James S. Hanley, assistant professor of otorhinolaryngology.
Dr. Aaron Bell, assistant clinical professor of neurology.
Dr. Mary E. O'Sullivan, assistant clinical professor of neurology.
Dr. John C. McCauley Jr., assistant professor of orthopedic surgery.
Dr. Philip Paley, assistant clinical professor of orthopedic surgery.
Dr. William A. Walker, assistant clinical professor of orthopedic surgery.
Dr. Katharine G. Dodge, assistant professor of pediatrics.
Dr. Rosa Lee Nemir, assistant professor of pediatrics.
Dr. Robert S. Hotchkiss, assistant professor of urology.
Dr. Ruth M. Bakwin, assistant clinical professor of pediatrics.
Dr. Lester Breidenbach, assistant clinical professor of surgery.
Dr. Elmer I. Huppert, assistant clinical professor of surgery.
Dr. Kenneth M. Lewis, assistant clinical professor of surgery.
Dr. William M. Dick, assistant clinical professor of otorhinolaryngology.
Dr. Eugene H. Moyle, assistant clinical professor of otorhinolaryngology.
Dr. James B. Shannon, assistant clinical professor of otorhinolaryngology.

NORTH CAROLINA

Faculty Appointments at New Bowman Gray School of Medicine.—Wake Forest College School of Medicine recently announced appointments to the faculty of the school, which will move to Winston-Salem, assuming the name Bowman Gray School of Medicine of Wake Forest College, when buildings are completed, probably in 1941. Dr. Howard H. Bradshaw, associate in surgery, Jefferson Medical College of

Philadelphia, has been appointed professor and director of the division of surgery; Dr. Herbert S. Wells, assistant professor of physiology, Vanderbilt University School of Medicine, Nashville, will become professor of physiology and pharmacology, and Dr. Leroy J. Butler, chief pediatrician at North Carolina Baptist Hospital, Winston-Salem, has been appointed professor of pediatrics. Others include Dr. Robert B. Lawson, instructor in pediatrics, University of Rochester School of Medicine, Rochester, N. Y., to be assistant professor of pediatrics, and Dr. George T. Harrell Jr., assistant in medicine, Duke University School of Medicine, Durham, assistant professor of medicine in charge of laboratory diagnosis. An arrangement has been made by which the University of North Carolina School of Public Health and Preventive Medicine, Chapel Hill, will teach those subjects in the Bowman Gray school. To this end the following members of the university faculty have been appointed to the Bowman Gray faculty:

Dr. Milton J. Rosenau, dean of the university school of public health, appointed lecturer in preventive medicine and public health.

Herman Glenn Baitz, Sc.D., appointed lecturer in public health.

Dr. John W. Roy Norton, appointed lecturer in preventive medicine and public health.

Dr. William Leroy Fleming, appointed lecturer in preventive medicine and public health.

Thus the university school of public health and preventive medicine, which cooperates closely with the state board of health, supplies the teaching for those subjects at the three medical schools of the state: the university, the Bowman Gray school and Duke University School of Medicine, Durham.

OREGON

State Medical Meeting at Eugene.—The sixty-sixth annual meeting of the Oregon State Medical Society will be held in Eugene, September 4-7, with headquarters at the Masonic Temple and under the presidency of Dr. Charles E. Hunt, Eugene. The meeting is planned as a postgraduate course with four guest speakers lecturing three times each on related subjects. They are:

Dr. Fred M. Smith, Iowa City: Diagnosis and Treatment of Coronary Artery Disease; Cardiac Therapy; Prognosis and Treatment of Rheumatic Heart Disease.

Dr. Hans Lissner, San Francisco: Indications for and Proper Use of Synthetic Male Hormone, Testosterone Propionate; Newer Synthetic Female Sex Hormone Preparations, Stilbestrol and Estradiol Dipropionate and Their Administration; Obesity and Leanness.

Dr. Donald V. Trueblood, Seattle: Lesions of the Lip, Oral Cavity and Jaw; Tumors of Soft Tissue Origin, Including the Neck; Tumors of the Breast.

Dr. Arthur Steindler, Iowa City: Foot Ailments; Low Back Pain; Disabilities About the Shoulder Joint.

A symposium on "Fluid Administration by Parenteral Methods" will be presented by four Portland physicians: Drs. Albert W. Holman, Louis P. Gambee, Homer P. Rush and Thomas D. Robertson. Other Oregon physicians to appear on the program include:

Dr. Blair Holcomb, Portland, Education of the Diabetic Patient.

Dr. Morton J. Goodman, Portland, Paroxysmal Flutter of the Diaphragm Simulating Coronary Thrombosis: Report of Unusual Case Controlled by Refrigeration of the Phrenic Nerve.

Dr. Charles P. Wilson, Portland, Disturbance of Function versus Functional Disturbance.

Drs. Charles D. Donahue and Ronald C. Romig, Eugene, Use of Avertin as a Basal Anesthesia in the Elderly Urologic Patient.

Dr. Martin A. Howard, Portland, Surgical Management of Gallbladder Disease.

The annual banquet will be Friday, September 6, and the golf tournament Saturday, September 7, at the Eugene Country Club.

PENNSYLVANIA

Society News.—Speakers at a meeting of the Lycoming County Medical Society, Williamsport, July 12, were Drs. Edward Lyon Jr. on "Etiology and Treatment of Hypertension"; Lloyd E. Wurster, "Simple Technic for Rapid Roentgen Pelvimetry," and Harold L. Tonkin, "Some Aspects of Coronary Disease."—Dr. Robert A. Matthews, Philadelphia, addressed the Cambria County Medical Society, Johnstown, July 11, on "Diagnosis and Management of Certain Psychiatric Problems Encountered in General Medical Practice."

High School Essays on Socialized Medicine.—The Schuylkill County Medical Society sponsored an essay contest on socialized medicine in the high schools of the county and awarded four prizes on the graduation days in June. The subjects were "Harmful Effects of Socialized Medicine to the Medical Profession" and "Harmful Effects of Socialized Medicine to the State and Nation." First and second prizes of \$15 and \$10 respectively were offered, and the best essays from each school were chosen by committees of teachers and physicians. The first prize essays were published by the leading county newspapers. Dr. Albanus S. Ryland, Pottsville, is chairman of the public relations committee of the society.

Philadelphia

Dr. Coates Becomes Professor Emeritus.—Dr. George M. Coates, professor of otolaryngology, University of Pennsylvania School of Medicine since 1933, has been made professor emeritus. He will continue as professor of otorhinology in the Graduate School of Medicine, a position he has held since 1917.

Personal.—Dr. Ralph Pemberton was recently elected an honorary fellow of the Royal Society of Medicine of England.

—Dr. Eleanor Scott, Philadelphia, received the current Mary Putnam Jacobi fellowship awarded by the Woman's Medical Association of the City of New York. She will continue her work in cancer research with Dr. Catharine MacFarlane at the Woman's Medical College of Pennsylvania. —Dr. Joseph Stokes Jr. went by clipper to France, August 4, to make a survey of the medical and public health needs of refugees in southern France under the auspices of the American Friends' Service Committee, it is reported.

Dr. and Mrs. Lewis Join Wistar Institute.—Dr. Warren H. Lewis, research associate in the department of embryology of the Carnegie Institution of Washington and professor of physiological anatomy at Johns Hopkins University School of Medicine, Baltimore, has retired from those positions and been appointed a member of the Wistar Institute of Anatomy and Biology as of July 1. Mrs. Lewis, also research associate at the Carnegie Institution laboratory, will carry on her work at Wistar Institute; it will be maintained by the Carnegie Institution as in the past years. The International Cancer Research Foundation is continuing to assist the investigations of Dr. and Mrs. Lewis.

SOUTH CAROLINA

Personal.—Dr. William H. Lacey, Blackville, has been appointed health officer of Georgetown County to succeed Dr. George S. T. Peebles, now with the state department of health. —Dr. Charles Fred Williams, superintendent of the South Carolina State Hospital, Columbia, received the honorary degree of doctor of laws at the June commencement of the University of South Carolina. —Dr. Yeadon M. Hyer, Chester, has been appointed health officer for Hampton and Allendale counties.

Society News.—Dr. Idys Minis Gage, New Orleans, addressed the Columbia Medical Society recently on "Surgery of Acute Cholecystitis" and Dr. George T. McCutchen, Columbia, "Some Advances in Plastic Surgery." —Drs. Isaac H. Grimbail and Thaddeus B. Reeves addressed the Greenville County Medical Society, Greenville, recently on medical and surgical treatment, respectively, of pyloric stenosis. —Dr. Wallace B. Bradford, Charlotte, N. C., addressed the Anderson County Medical Society, Anderson, July 10, on "Sterility in the Female." —Drs. William D. Hazlehurst and Douglas B. Rensen, Charleston, addressed the Medical Society of South Carolina, Charleston, June 25, on "Craniopharyngioma" and "Primary Subarachnoid Hemorrhage" respectively. A portrait of the late Dr. Edward F. Parker, Charleston, at one time president of the society, was presented at the meeting.

VIRGINIA

New Health Officers.—Dr. Earle C. Gates, Bristol, has been appointed health officer of a new unit in Chesterfield County. Dr. Robert Bruce Mallet, Baltimore, has been appointed health officer of Orange County, a new unit that opened July 1. Dr. William P. Terry, Victoria, has been appointed in Charlotte County and Dr. James M. Suter, Jonesville, in Washington County to succeed Dr. William M. Moir, Bristol, who goes to Smyth County.

Symposium on Industrial Health.—The Medical College of Virginia, Richmond, will present a two day symposium on industrial health at the college, September 12-13, under the sponsorship of the department of preventive medicine. Among the speakers will be:

Dr. Carl M. Peterson, secretary, Council on Industrial Health, American Medical Association, Chicago.

Dr. Robert A. Kehoe, Cincinnati, Industrial Lead Poisoning.

Dr. Anthony J. Lanza, New York, A Medical Setup for a Small Industrial Plant.

Dr. Victor G. Heiser, New York, Do Good Working Conditions Pay?

Dr. Bayard T. Horton, Rochester, Minn., Peripheral Vascular Disease in Industry.

Dr. George H. Gehrmann, Wilmington, Del., Objectives of Health Examinations and Their Industrial Applications.

Mr. L. B. F. Raymond, Philadelphia, An Industrialist Looks at Employee Health.

There will be a registration fee of \$5.

WEST VIRGINIA

State Medical Election.—Dr. Robert King Buford, Charleston, was elected president of the West Virginia State Medical Association at the annual meeting in White Sulphur Springs, July 29-31, held jointly with the Medical Society of Virginia. Dr. Buford will take office January 1. Vice presidents elected are Drs. Marvin H. Porterfield, Martinsburg, and Desausseur G. Preston, Lewisburg. The 1941 meeting will be in Charleston.

GENERAL

Special Society Meeting.—Dr. Isaac H. Jones, Los Angeles, was elected president of the Pacific Coast Oto-Ophthalmological Society at its annual meeting June 24-28 in Spokane. Vice presidents elected were Drs. Augustus B. Dykman, Portland, Ore., and Leroy R. Pugmire, Ogden, Utah; Dr. Clifford Allen Dickey, San Francisco, was reelected secretary. The guest speakers were Drs. French K. Hansel and Meyer Wiener, St. Louis, and Walter B. Lancaster, Boston.

Results of Board Examinations.—The American Board of Obstetrics and Gynecology at its examinations held in Atlantic City, N. J., in June granted certification to 191 of 242 candidates. The next examinations for group B, part I, candidates will be given Jan. 4, 1941, and for group A and group B, part II, at Cleveland in June 1941 immediately prior to the meeting of the American Medical Association. Applications may be obtained from Dr. Paul Titus, 1015 Highland Building, Pittsburgh (6), Pa.

Biological Photographic Association.—The tenth annual convention of the Biological Photographic Association will be held at the Hotel Schroeder, Milwaukee, September 12-14. The program will offer papers and discussions, with a salon of natural color and monochrome prints of biologic and clinical subjects. The association has offered its cooperation to the War Department in connection with a plan to organize clinical illustration units in the medical division in time of war. A questionnaire has been distributed and discussion of the plan will be in order at the meeting.

Railway Surgeons' Meeting.—Dr. George M. Williamson, Grand Forks, N. D., was elected president of the Great Northern Railway Surgeons' Association at the annual meeting in Spokane, Wash., June 28-29, and Dr. Roscoe C. Webb, Minneapolis, was reelected secretary. Among speakers at the meeting were Drs. Ernest D. Lamb, Klamath Falls, Ore., on "Fractures of the Phalanges"; Joseph W. Lynch, Spokane, "Diagnosis and Treatment of Intracranial Hemorrhages Complicating Head Injuries"; Henry W. Power, Conrad, Mont., "Treatment of Burns," and Donald G. Corbett, Spokane, "Traumatic Injuries to the Urinary Tract."

Tuberculosis Deaths Decline.—In 1939 there were 61,184 deaths from tuberculosis in the United States as compared with 63,677 in 1938, the *Bulletin* of the National Tuberculosis Association reports. The death rate dropped from 48.9 per hundred thousand of population in 1938 to 46.6 in 1939. Except for Delaware, the death rate in all states declined or remained within one decimal point higher than the 1938 figures. The lowest rates were in Nebraska (15.8), Utah (16.8), Iowa (18.5), Idaho (19.7) and North Dakota (20.2). The highest was in Arizona (191), but that was a decline from the 1938 rate of 221.6. The New Mexico rate remained the same, 91.2 for both years. The rate in the District of Columbia declined from 92.2 to 88.3.

Age Limit for Mine Workers Raised.—An order declaring employment in coal mines hazardous for minors between 16 and 18 years of age was issued, August 2, by Miss Katharine F. Lenroot, chief of the Children's Bureau of the U. S. Department of Labor. The order applies to both anthracite and bituminous mines whose products are shipped in interstate commerce. It declares that all occupations in underground mines and in the pits of coal stripping operations are hazardous. Some surface occupations are excepted, such as those in offices and repair or maintenance shops. In an investigation of the situation the Children's Bureau was assisted by an advisory committee representing coal operators, organized labor, safety experts, insurance interests and the public. The investigation showed that the accident risk in coal mining exceeds that in practically any other industry and that in underground work the risk is far greater than that of any other industry for which figures are available. Miss Lenroot pointed out that the employment of boys in coal mining has greatly decreased in the last decade and that employers realize the great hazards involved.

Bequests and Donations.—The following bequests and donations have been announced in recent months:

Cooper Hospital, Camden, N. J., \$320,000 from the Campbell Soup Company to build a wing as a memorial to Dr. John Thompson Dorrance, late president of the company.

Chester County Hospital, \$3,000, and Homeopathic Hospital, \$5,000 from the will of Mabel S. Matlack, West Chester, Pa. Both hospitals are in West Chester.

Montgomery County Hospital, Norristown, Pa., \$2,000 by the will of the late William Stephens, New Centerville.

Germantown Hospital, Philadelphia, \$2,000 by the will of Miss Harriet Huntley.

Episcopal Hospital, Philadelphia, \$15,000 to endow three beds, a bequest from Miss May F. Currie, a public school teacher.

Rochester (N. Y.) Academy of Medicine, \$1,000 by the will of the late Mrs. Jennie P. Roe, in memory of her husband, Dr. John O. Roe.

Shelton General Hospital, Shelton, Wash., \$25,000 as a gift from Mrs. Agnes H. Anderson, Seattle.

Children's Hospital of Boston, Boston Lying-In Hospital, Boston Association for the Relief and Control of Tuberculosis, Boston Floating Hospital, New England Peabody Home for Crippled Children, \$5,000 each by the will of William A. McKenney, Brookline, Mass.

Jewish Hospital Association, Philadelphia, \$2,500 by the will of Charles Walker, to be used for care of ward patients.

Philadelphia Home for Incurables, \$25,800, and the University of Pennsylvania Hospital, \$13,287 from the estate of Miss Emma C. Gratz, who left the fund in trust at her death in 1921.

Pennsylvania Hospital, Philadelphia, and Massachusetts General Hospital, Boston, will share one third of an estate of \$3,500,000 left by the Rev. Alexander G. Mercer, who died in 1882. The estate was left in trust and the last beneficiary died in 1938.

FOREIGN

Yellow Fever on Ship from South America.—Five cases of yellow fever among the crew of a British ship that arrived in Londonderry, Ireland, were reported in a cable to the *New York Times*, August 9. It was said that the disease was discovered after the ship had touched at Freetown, West Africa. One of the patients died. It was suspected that two pet monkeys carried the disease aboard. One monkey died and the other was destroyed.

CORRECTION

Meeting of Southeastern Surgeons in Miami.—The Florida section of the Southeastern Surgical Congress will hold its seventh annual clinical conference, August 31, at the James M. Jackson Memorial Hospital in Miami and not at the Jackson Memorial Hospital, Dade City, as noted in *THE JOURNAL*, August 10, page 467.

Government Services

Changes in Public Health Service

The following changes in assignments have been announced by the U. S. Public Health Service, among others: Medical Director George W. McCoy, relieved at New Orleans and ordered to the National Institute of Health, Washington, D. C.; Medical Director Eugene H. Mullan, relieved at Ellis Island and ordered to Montreal, Canada, for duty, and Surgeons Albert E. Russell and Edgar W. Norris Jr., relieved at Chicago and Hot Springs, Ark., and ordered to district number 1, New York, and Baltimore for duty, respectively; Surgeon Winfield K. Sharp Jr., relieved at New Orleans and ordered to Washington, D. C., for duty.

Physicians Wanted for CCC Duty

The Surgeon of the Seventh Corps Area announces that physicians are needed for the medical service of the Civilian Conservation Corps. The initial salary is \$3,200 a year. No quarters are provided for families, and the physicians are required to pay for their own food at camps. Temporary quarters for physicians are provided at the camps for a nominal fee. Those selected must pay their travel expenses to the headquarters of the district, where they are placed on temporary duty before being sent to camp. The principal duties at camps consist of the medical care of the enrollees and the practice of preventive medicine. To be eligible, the physician must be a citizen of the United States, a graduate of an accredited medical school, licensed to practice medicine and physically able to perform the duties. Physicians over 60 years of age are not ordinarily employed. Those interested are requested to submit applications to the Office of the Surgeon, Headquarters, Seventh Corps Area, Federal Building, Omaha, giving date on which available and preference of assignment in the following states: Minnesota, North Dakota, South Dakota, Iowa, Nebraska, Missouri, Kansas and Arkansas.

Protection of the Soldier in Warfare

At the Section of Surgery of the Royal Society of Medicine, a discussion took place on what the chairman, Mr. Zachary Cope, called "the physical prophylaxis of wounds." Mr. Kenneth Walker (*THE JOURNAL*, May 18, p. 2043), said that in the last war he noted how many men were killed by small missiles entering the chest and ripping up one of the great vessels or the heart. The principle that it was worth while protecting the head by means of a steel helmet had been recognized. The old objection to armor—that it would overload the soldier—no longer held. The man to be protected did not march but was carried by lorry, motorcycle or airplane. Moreover, steel of great tensile power was now available, as well as other suitable materials. Armor to protect against armor-piercing bullets necessitated a weight of 20 pounds, but 60 per cent of the wounded arriving at casualty clearing stations were injured by other missiles, mostly by trench-mortar splinters. Mr. Walker showed specimens of compressed fiber, including bakelite, which had the same tensile power as aluminum but half its weight. It would protect against shrapnel. During the Hitler régime three unsuccessful attempts had been made to induce a certain American inventor of armor to equip the German armies.

Sir Richard Cruise (ophthalmologist) described his duralumin visor. He hoped that no steel helmets would be issued in future without this attachment. From figures which he worked out in 1917 he found that from 50 to 70 per cent of war blindness was preventable.

Sir Harold Gillies (plastic surgeon) said that the War Office should consider the question of extra wind screens which would protect the driver. Frequent in war were burns of the hand caused by placing it in front of the face when exposed to flame. The result was extensive burns of the back of the hand, producing stiff joints. A gauntlet would give protection without interfering with the use of the hand in driving.

Mr. Ogier Ward referred to many casualties from missiles directed from above. The natural reaction was to crouch, and therefore there had been many wounds of the buttock and back. The British helmet, which he thought inferior to the German, afforded no protection to the temple and no protection behind. He suggested a curtain of chain mail attached to the back of the helmet and coming down to the seventh cervical vertebra.

Mr. E. D. D. Davis (laryngologist) said that the British helmet was as good as the German, which was 14 ounces heavier. In the last war Harvey Cushing published a number of photographs showing extensive injury to the helmet, yet the wearer sustained only scalp wounds. The German helmet was more easily seen and its contour was such that it was less efficient in warding off missiles.

Some speakers objected that the weight carried by the soldier must not be increased. Mr. T. B. Layton was absolutely opposed to the addition of any weight to the British soldier's equipment, but he had been impressed by the protection afforded by something in the pocket covering a vital area and weighing about 2 ounces.

Mr. Kenneth Walker in reply quoted a war correspondent to the effect that the Germans were using body armor. It would be possible to produce something weighing 2 ounces to cover the heart and give more protection than a book or flask carried in the breast pocket.

RESOLUTIONS OF THE SOCIETY

The following resolutions were unanimously adopted:

"That this representative meeting of the Royal Society of Medicine, after full discussion of the question, is emphatically

of the opinion that the physical protection of the members of the fighting forces can and should be improved by a closer collaboration between the medical profession and the appropriate technical experts of the Admiralty, War Office and Air Ministry.

"That this meeting of the Royal Society of Medicine resolves that the Council be asked to consider the formation of a special committee to this end. As the matter is one of extreme urgency and importance, it is hoped that the president may use his emergency powers and approach the government with the offer of the society's cooperation at the earliest possible date."

The Workmen's Compensation Acts: Foot Drop as an "Accident"

The workmen's compensation acts entitle a man to compensation for incapacity due to an "accident" "arising in or out of his employment." The word accident was never defined, but by a series of judgments in the courts has been given the widest possible scope so as to cover anything which in any way can be connected with employment. This wide interpretation has again and again been contested but without success. Each judgment in favor of the workman has furnished a precedent for further extension. Thus a workman collapsed and died while turning a nut with a spanner. There was no evidence of undue strain, and the necropsy showed a ruptured large aneurysm of the aorta in an advanced stage. Medical evidence was given that the rupture might have easily occurred in his sleep. But the court held that it was an "accident" within the meaning of the act. Cases of sunstroke and lightning stroke while at work have been held to be "accidents." An employer is liable for injury even when a workman acts in direct violation of his orders. A man who was receiving compensation was sent to prison for theft. Though this of course prevented him from earning any wages, the judge held that he was entitled to the continuance of the weekly compensation payments. The result of the compensation acts has become a huge burden on industry, amounting to about \$60,000,000 annually paid in respect to about 500,000 "accidents." The latest case contested in the courts, with the usual result, was the following:

A man employed in building pillars to support the roof of underground workings in a coal mine suffered from foot drop as the result of pressure on the peroneal nerve in the crouching position in which he had to work. The arbitrator of the claim for compensation held that the incapacity was not the result of an accident arising out of or in the course of his employment. This decision was reversed by a higher court. The employers appealed against this judgment and the case was taken to the highest court, the House of Lords, which decided in favor of the workman. Giving judgment, the lord chancellor said that it was admitted that the man's incapacity had arisen out of his employment and the only question was whether it was due to accident. The phrase "injury by accident" as used in successive workmen's compensation acts had been the subject of repeated and elaborate discussion and in the course of forty years a gradual but steady extension of its meaning could be traced. The early cases seemed to have been decided on the basis that "accident" was some fortuitous and unexpected event, as in policies of insurance. In the first case which came to the House of Lords a decision was given in favor of a workman who ruptured himself in an act of overexertion. It was held that "accident" was not a legal term with clearly defined meaning but meant any unintended and unexpected occurrence. This decision opened the door to claims which had previously failed. It was next decided that a man who contracted anthrax in wool sorting had suffered "an accident." But two cases of "beat hand" and one of "beat knee" were decided in favor of the employer on the ground that the injury was the inevitable result of long continued work. Thus a claim in respect to a progressive

disease failed. But later a man suffering from chronic heart and kidney disease one day had to stop owing to sudden pain and choking. The judge held that his hard work induced breakdown of his enfeebled heart. This involved a definite change in his condition on the day in question and therefore his claim succeeded. In the present case the lord chancellor said that it was impossible to distinguish it in principle from a case of foot drop. The pressure on the peroneal nerve during the last spell of work produced the paralysis. The man sustained a definite physiologic injury in his work. The fact that for a month previously he had felt some loss of power in no way affected his right to compensation.

Red Cross Funds

The British Red Cross has raised \$9,000,000. On behalf of the American Red Cross Mr. Joseph Kennedy, the Ambassador, has broadcast an appeal to Americans in which he said that everything indicated that England would be called on to meet the greatest siege in history. To relieve the suffering a committee of the American Red Cross had been set up in this country, of which Mr. Daniel Grant had agreed to be chairman and he himself honorary chairman. Already the American Red Cross had made expenditure in Britain amounting to \$500,000 and a further \$5,000,000 had been collected. Bombs had fallen on the English countryside and villages, and the fervent gratitude of Americans was that their children were not liable to be killed in their beds at any time.

Control of Blindness

A decree has been issued by the president of Argentina creating a national foundation of the blind with authority to supervise all public and private state subsidized institutions for the protection and education of the blind. It is to recommend administrative and legal measures for the care of the blind and to handle endowments intended to combat blindness.

The connection between gonorrheal conjunctivitis and the use of Credé's method, the infiltration of silver nitrate in the conjunctival sac of the newborn, in South America was discussed by A. Vázquez Barriera in the *Revista oto-neuro-oftalmológica y de cirugía neurológica sud-americana* (14:79 [Nov.] 1939). According to his figures blindness, as ascertained in the national institute for the blind, was found to have been caused in 114 cases (35.6 per cent) by conjunctivitis of the newborn. This percentage is much greater in Brazil (48 per cent). In São Paulo it amounted to 40 per cent. In Colombia among forty inmates of the Colombian institute for the blind it amounted to 25 per cent. In the state institute for the blind in Uruguay the percentages ranged from 42 in 1917 to 39 in 1926 and to 36.5 in 1938. In Argentina, where every province has sovereign power, Credé's method is compulsory in only three, in Brazil in only nine federal states. Some of the federal states in Brazil, however, require that cases be reported. No appropriate legislation exists either in Colombia or in Peru, though the clinics and maternity hospitals usually employ the method. In Lima, for example, though gonorrhea was discovered in 41 per cent of the mothers, only one or two cases were found in about 7,000 babies. Suppurating conjunctivitis must be reported in Peru. In Uruguay Credé's method has been compulsory since 1924. The national committee for the prophylaxis of blindness distributes dropping bottles containing the solution to all midwives free of charge. In Uruguay, Paraguay and Venezuela cases must be reported by the physician. However, the use of Credé's method is not compulsory either in Paraguay or in Venezuela.

Hookworm Disease

Ancylostomiasis plays an important part in the disease control program of Argentina. In 1924 a law made treatment for hookworm obligatory throughout the country. Infested regions were specified and the control carried out jointly by the authorities involved. Persons infested with worms must prove that they are under treatment. If they cannot furnish proof they are consigned to one of the institutes and treated without charge. If persons refuse to be treated they may be isolated in their homes. Homes, factories and schools in infested regions must be equipped with the required sanitary arrangements. Transfer of ownership of houses may not be completed notarially until the local sanitary boards have accepted the sanitary arrangements. The law of 1924 was supplemented by regulations containing enforcement provisions. In these the northeastern provinces and territories regarded as hookworm infested were designated. These regulations have not yet gone into effect.

The first case of hookworm in Argentina was reported in 1885. The patient was an Italian aged 26 who had previously worked as a laborer in the construction of the St. Gotthard tunnel in Switzerland. In parts of the Argentine province of Santa Fe 70 per cent of 633 persons examined in 1938 were found to be infested (Huarque Falcon, J.: *Sem. Méd.* 47:1135 [May 9] 1940). A recent monograph by Dr. Reynaldo Agrelo, an assistant in the department of social medicine and hygiene in the faculty of medicine of Buenos Aires, considers hookworm disease together with malaria as the most serious threat to the inhabitants of the interior provinces. According to this monograph, only from 15 to 20 per cent of the young men in the province of Corrientes were fit for military service because of ancylostomiasis. Undernourishment due to the great poverty found among the inhabitants of these regions was a secondary cause. Dissemination of the disease is helped by the general custom prevalent there of walking barefooted. What is needed is money and the authorization of the government agencies to establish an increased prophylaxis.

Incidence of Leprosy

The *Boletín de la Oficina sanitaria panamericana* (19:508 [May] 1940) discusses the prevalence of leprosy in the world. Twenty-five years ago, when the Far East was regarded as the chief source of the disease, Victor Heiser estimated the total number of lepers at 2,000,000. The spread of leprosy in Africa was not known at the time. Sir Leonard Rogers estimated the total number of lepers at 3,000,000, with this distribution: China 1,000,000, India 1,000,000, Africa about 500,000, Russia 150,000, Latin America 60,000, Siam 15,000, the Philippine Islands 12,000, Europe 7,000, Australia about 5,000, United States and Canada about 100 and the remaining countries about 35,000. Muir computed a still higher incidence, assuming from two to three early cases for each advanced case. Today it is believed that there are from five to ten million leprosy persons, 5,400 for every million of the world's inhabitants. In the Western Hemisphere the situation warrants serious consideration but is not alarming. According to recent statistics there are fewer than 100,000 lepers in North and South America, from 35,000 to 50,000 being in Brazil, 12,000 in Colombia, from 8,000 to 10,000 in Argentina, from 4,000 to 6,000 in Mexico, from 2,000 to 5,000 in Paraguay, from 2,000 to 4,000 in Cuba, about 2,000 in the French colonies, from 1,000 to 2,000 in Venezuela, more than 1,500 in Dutch Guiana, about the same number in British Guiana, about 1,200 in the United States, 1,000 in Trinidad, from 500 to 1,000 in Uruguay, several hundred in Chile and Peru, about 200 each in Ecuador and Barbados, Haiti, Jamaica, Bolivia, Costa Rica, Dominican Republic, Guatemala, Honduras, Nicaragua, Salvador and the Virgin Islands, from 150 to 200 in Puerto Rico, more than 100 in Panama and fewer than 100 in Canada. The South Pacific regions are least

affected. Continental Chile is considered free from the disease. However, Easter Island, belonging to Chile, is practically a leper colony in which hundreds of leprosy persons enjoy unrestricted liberty.

Society News

The newly organized Argentine Society of Medical Psychology and Psychoanalysis, an affiliate of the Argentine Medical Association, held its first meeting July 5. Prof. Juan Ramón Beltrán, professor of the history of medicine and president of the new society, pointed out in his opening address the lack of philosophical and humanistic training in the education of present day medical students. Purely technical and scientific studies make for a one-sided product. The training of medical students in psychology in Argentina, he said, was too elementary. Psychology needed to be studied in its application to medicine. Prof. Gonzalo Bosch delivered a lecture on the significance of psychology and psychoanalysis in present day medicine.

The newly founded Latin-American Society of Plastic Surgery (Sociedad Latinoamericana de Cirugía Plástica) met for the first time in São Paulo, Brazil, July 4 and 5. Brazil, Argentina, Uruguay, Chile and Peru were especially well represented. Numerous papers were read and demonstrations made.

PHILIPPINE ISLANDS

(From a Special Correspondent)

July 1, 1940.

Psychiatry in the Philippines

At the inaugural meeting of the Philippine Society of Psychiatry and Neurology March 2, held at the Scientific Hall of the National Psychopathic Hospital, Mandaluyong, Rizal, the consulting psychiatrist and neurologist of the bureau of health, Dr. Maximilian Silbermann, stressed the importance of the Philippines as a comparatively new field for research work in medical psychology. Dr. Silbermann had studied and worked with Dr. Otto Potzl and Dr. Wagner von Juaregg of Vienna before coming to the Philippines. He pointed out that, as a tropical country, the Philippines offers unique opportunities to the research worker to study the influence of the climate on the development and causes of nervous and mental diseases and to investigate special types found here. "The fact that practically all textbooks on tropical diseases devote only very brief chapters to nervous diseases or make no mention of them at all shows how little scientific work has been done in this direction," Dr. Silbermann said. Dr. Demetrio Lacuna, chief of the National Psychopathic Hospital, traced the progress of the work in the care and treatment of psychotic patients in the Philippines. As early as 1782, an asylum for the insane was founded by Señor Francisco Gomez. But the real beginning of modern psychiatric work in the Philippines was in 1918, thanks to the pioneering efforts of Dr. Elias Domingo. In 1928 the National Psychopathic Hospital was founded and placed under the supervision of the bureau of health.

The hospital plant occupies 60 hectares of land, 9 kilometers from the center of Manila. There are one administration building, five concrete pavilions for the inmates of the institution, two big dormitories for the male and female nurses and attendants, a separate mess hall and kitchen, five cottages for physicians plus six now under construction, a new and separate building for the laboratory and the pharmacy, a storeroom, a garage, one basketball court and three tennis courts. A plan is afoot to erect a separate building to become the clinic for nervous diseases with a bed capacity of 300. It will serve both as a receiving unit and a hospital for acute cases amenable to treatment and for diagnostic and intensive research work. It will also be a training center for staff physicians, nurses, university students and attendants, besides being an information center on medical psychology for the entire country.

Marriages

HARRY H. HENDERSON, Wheeling, W. Va., to Miss Regina Barbara Vaschak of Youngstown, Ohio, in Washington, D. C., June 15.

WILLIAM HUGH PATTON JR., Morganton, N. C., to Miss Ruth Briscoe of Winona, Miss., in Clarksdale, Miss., July 8.

ARTHUR MORTON SMITH JR., Charlottesville, Va., to Miss Elizabeth Wood Borst of White Plains, June 22.

KATHERINE M. CLOSE to Rev. Herbert B. Smith, both of Los Angeles, at St. Helena, Calif., July 15.

JOSEPH P. HOLT, Versailles, Ky., to Miss M. Elizabeth Walter of Anna, Ill., in Champaign, Ill., June 7.

GEORGE ALFRED MITCHELL, Clinton, Mo., to Miss Ann Katherine Ulmer of St. Louis, June 30.

JULIEN HERMAN MEYER, Enfield, N. C., to Miss Dorothy Rose Kahn of Richmond, Va., July 14.

MAX KRAKAUER, Davenport, Iowa, to Miss Mary Alice Dawson of Portsmouth, Ohio, June 7.

JAMES FENDALL PARKINSON JR., Chester, Va., to Miss Sarah Frances Williams of Scottville, July 3.

CLIFFORD MATHEW SCHNIDT, Newton, N. J., to Miss Eleanor Elizabeth Meyer of Andover, July 13.

EMERSON R. HATCHER, Berea, Ky., to Miss Jane Louise Springer of Columbus, Ohio, July 24.

ARTHUR LAMLEY LENNON, Adrian, Mich., to Miss Elizabeth Karns of Chambersburg, Pa., July 8.

GORDON HARVEY SPRAGUE to Miss Margaret Scott, both of Cincinnati, at Liberty, Ind., June 27.

HENRY SALTONSTALL, Milton, Mass., to Miss Cecilia Beaux Drinker of Merion, Pa., July 27.

EARLE B. KAY, Ann Arbor, Mich., to Dr. DOROTHY MAE IRIE of Grand Rapids, June 18.

WILLIAM BENJAMIN HOOVER to Miss Sallie Frances Perdue, both of Richmond, Va., June 22.

HARVEY ERNEST JORDAN JR., University, Va., to Miss Janet Robinson of Hampton, July 13.

ROBERT HARDIE ENGLEADOW, Anahuac, Texas, to Miss Sara Thurman of Commerce, June 8.

GEORGE CALVIN BRYANT JR. to Miss Novella Bernice Dodson, both of Dallas, Texas, May 20.

RALPH T. RANK, Milwaukee, to Miss Marie J. Foeller of Green Bay, Wis., June 17.

JOSEPH W. STECKBAUER to Miss Frances Zendala, both of Manitowoc, Wis., May 25.

AUGUSTUS B. KUHLMAN JR. to Miss Sara Ellen Marti, both of Davenport, Iowa, May 25.

GEORGE D. REAY, Onalaska, Wis., to Miss Frances Robb Wise of Hayward, June 8.

MITCHELL L. MORAN to Miss Irene Batchelder, both of St. Petersburg, Fla., June 12.

SVERRE QUISLING, Madison, Wis., to Miss Virginia Constance Moe of Goodman, June 8.

RICHARD L. MEILING to Miss Ann Elizabeth Lucas, both of Columbus, Ohio, in June.

WILTON E. TUGWELL to Miss Virginia Noel Johnson, both of Pensacola, Fla., May 10.

NATHAN B. LEWIS to Miss Olga Douglas, both of Vicksburg, Miss., June 28.

HERBERT BRYAN HUTT to Miss Nancy Evans, both of Youngstown, Ohio, June 29.

LEONARD S. MARKSON, Milwaukee, to Miss Edith Sherin of New York, June 14.

ANTHONY J. SANFELIPPO to Miss Lorraine Connolly, both of Milwaukee, June 22.

JOSEPH H. FRIES to Miss Marilyn Ronda Wetstone, both of Brooklyn, June 16.

JAMES JENNINGS GAUNT to Miss Alice Mary Bruce, both of Milwaukee, July 6.

LOYD B. GREENE to Miss Rosalind Lamb, both of Philadelphia, May 25.

FRANK E. WENZKE, Dayton, Ohio, to Miss Rita Norman in Xenia, June 22.

CONDE F. CONROY to Miss Margaret Murphy, both of Milwaukee, June 8.

Deaths

Stuart Pritchard * Battle Creek, Mich.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1905; member of the American Association for Thoracic Surgery and the American Clinical and Climatological Association; fellow of the American College of Physicians; past president and vice president of the National Tuberculosis Association and a member of the board of directors from 1928 to 1936; in 1936 founder of the Michigan Trudeau Society; in charge of the chest department of the Battle Creek Sanitarium from 1913 to 1930; since 1930 president and general director of the W. K. Kellogg Foundation; in 1928 delegate from the United States to the conference of the International Union Against Tuberculosis in Rome; in 1940 received the honorary degree of doctor of science from the University of Michigan, Ann Arbor; aged 58; died, August 4, of carcinoma of the thyroid.

Lisle Byron Kingery * New York; Cornell University Medical College, New York, 1918; member of the American Urological Association; fellow of the American College of Surgeons; served during the World War; attending urologist to the New York Hospital, New York, St. Agnes Hospital and New York Hospital, Westchester Division, White Plains, Grasslands Hospital, Valhalla; consulting urologist, Booth Memorial Hospital, New York, Northern Westchester Hospital, Mount Kisco, and the United Hospital, Port Chester; aged 46; died, July 11, in the Flushing (N. Y.) Hospital of coronary thrombosis.

De Witt Clinton Bryant * Claremont, Calif.; University of Wooster Medical Department, Cleveland, 1875; fellow of the American College of Surgeons; past president of the Nebraska State Medical Association and the Omaha-Douglas County Medical Society; formerly dean and professor of ophthalmology at the John A. Creighton Medical College, Omaha; at one time on the staffs of St. Joseph, Mercy and Swedish hospitals in Omaha; formerly mayor of Claremont; aged 91; died, June 30, in the Pomona Valley Community Hospital, Pomona, of hemorrhage from the pharynx.

John G. Wishard * Wooster, Ohio; Medical College of Indiana, Indianapolis, 1888; past president of the Wayne County Medical Society; founded the American Hospital in Teheran, Persia, and was its director for twenty years; past president of the Ohio State Student Health Association; for many years one of the five members of the Persian National Board of Health; author of "Twenty Years in Persia," and "Reminiscences of a Doctor"; aged 76; died, July 15, of coronary thrombosis.

Philip Du Bois Bunting, Elizabeth, N. J.; Yale University School of Medicine, New Haven, Conn., 1898; member of the Medical Society of New Jersey; past president of the Union County Medical Society; served during the World War; for many years member of the board of health; aged 62; on the staffs of Bonnie Burn Sanatorium, Scotch Plain, and the Rahway (N. J.) Hospital; served on the staff of the Elizabeth General Hospital, where he died, June 28, of tumor of the brain.

Christian Herman Diehl * Wood River, Ill.; St. Louis College of Physicians and Surgeons, 1908; for many years district health superintendent for the Illinois State Department of Public Health, and health officer of Roxana; formerly managing officer of the Lincoln (Ill.) State School and Colony; on the associate staff of the Alton (Ill.) Memorial Hospital; aged 60; died, July 17, in St. Joseph's Hospital, Alton, of hypertensive heart disease.

Alexander Joseph Douglas, Winnipeg, Man., Canada; Manitoba Medical College, Winnipeg, 1897; at one time professor of preventive medicine, hygiene and public health at his alma mater; past president of the Canadian Public Health Association; for many years medical health officer of Winnipeg; aged 66; died, June 30, in the Winnipeg General Hospital of a fractured rib and rupture of the liver and spleen.

William Graham Hinsdale, Syracuse, N. Y.; Medical Department of Tulane University of Louisiana, New Orleans, 1886; member of the Medical Society of the State of New York; formerly associate professor of obstetrics at the Syracuse University College of Medicine; aged 78; on the staff of the Crouse-Irving Hospital, where he died, July 15, of pernicious anemia.

Ray Glenn De Voist, Cincinnati; University of Michigan Homeopathic Medical School, Ann Arbor, 1914; at one time professor of hygiene and sanitation and of histology and embry-

ology at the Eclectic Medical College; superintendent of the Cincinnati Anti-Tuberculosis League; aged 52; died, July 12, in the Bethesda Hospital of carbuncle of the neck and diabetes mellitus.

Adelaide Brown * San Francisco; Cooper Medical College, San Francisco, 1892; an Affiliate Fellow of the American Medical Association; member of the state board of health from 1915 to 1931; lecturer on child hygiene, Stanford University School of Medicine from 1920 to 1936; obstetrician to the Children's Hospital from 1899 to 1915; aged 72; died, July 29.

John *Snell Holbrook * Mankato, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1896; fellow of the American College of Surgeons; at one time member of the school board; past president of the Blue Earth County Medical Society; on the staffs of St. Joseph's and Immanuel hospitals; aged 66; died, June 8, of coronary thrombosis.

Albert Sparr Rider * Flandreau, S. D.; Rush Medical College, Chicago, 1900; past president of the South Dakota State Medical Association; fellow of the American College of Surgeons; veteran of the Spanish-American and World wars; medical director of the Flandreau Indian School Hospital; aged 63; died, July 8, of coronary occlusion.

Robert Dixon Gibson, Youngstown, Ohio; Western Reserve University Medical Department, Cleveland, 1880; fellow of the American College of Surgeons; past president of the Mahoning County Medical Society; for many years on the staff of the Youngstown Hospital; aged 84; died, July 18, of carcinoma of the rectum with pulmonary metastases.

John Thompson Altman, Jonesboro, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1908; member of the Arkansas Medical Society; fellow of the American College of Surgeons; past president of the Craighead-Poinsett County Medical Society; on the staff of St. Bernard's Hospital; aged 57; died, July 17, of heart disease.

Frederick Tanquary Hyde, Lake Crescent, Wash.; Harvard Medical School, Boston, 1898; member of the Washington State Medical Association and the Pacific Coast Oto-Ophthalmological Society; at one time connected with the U. S. Public Health Service; served during the World War; aged 68; died, June 2, in a hospital at Seattle.

Carl Frederick Reppun, Honolulu, Hawaii; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, 1910; University of Moscow Faculty of Medicine, Russia, 1912; member of the Hawaii Territorial Medical Association; aged 57; died, June 7, in the Queen's Hospital of injuries received in an automobile accident.

Robert Bruce Gamble, Meadville, Pa.; University of Buffalo School of Medicine, 1896; member of the Medical Society of the State of Pennsylvania; veteran of the Spanish-American and World wars; fellow of the American College of Surgeons; on the staff of the Meadville City Hospital; aged 69; died, July 11.

George Andrews Holdridge, Foley, Minn.; University of Bellevue Hospital Medical College, New York, 1901; member of the Minnesota State Medical Association; member of the county board of commissioners; aged 61; died, July 3, in St. Cloud of injuries received in an automobile accident.

Anthony G. Wittman, Elgin, Ill.; Northwestern University Medical School, Chicago, 1905; member of the Illinois State Medical Society; veteran of the Spanish-American War; assistant managing officer of the Elgin State Hospital; aged 64; died, July 16, of bronchogenic carcinoma.

Edward Andrew Rowland, New York; University of Alabama School of Medicine, 1910; member of the American Psychiatric Association; on the staff of the Manhattan State Hospital, Ward's Island; aged 57; died, July 10, in the Neurological Hospital of brain tumor.

Robert C. Eve, Atlanta, Ga.; College of Physicians and Surgeons, Baltimore, 1892; veteran of the Spanish-American and World wars; formerly affiliated with the Veterans Administration Facility; aged 71; died, June 22, of carcinoma of the lung and myocarditis.

Willis Franklin Hart * Camden, Maine; Medical School of Maine, Portland, 1886; in 1918 member of the House of Delegates of the American Medical Association; on the staff of the Knox County General Hospital, Rockland; aged 80; died, June 25.

Daniel Howard Hope * Cape Girardeau, Mo.; Washington University School of Medicine, St. Louis, 1904; on the staffs of the Southeast Missouri Hospital and St. Francis Hospital; aged 61; died, July 4, in St. Luke's Hospital, Denver.

Taylor Wilson Funkhouser ☉ Danville, Ill.; Rush Medical College, Chicago, 1916; served during the World War; aged 50; on the staffs of St. Elizabeth Hospital and the Lakeview Hospital, where he died, July 18, of carcinoma.

Robert Earl Evans, Milledgeville, Ga.; Kentucky University Medical Department, Louisville, 1906; member of the Medical Association of Georgia; on the staff of the Scott Hospital; aged 58; died, July 8, of angina pectoris.

John Lee Calcote Jr., Hamburg, Miss.; Hospital College of Medicine, Louisville, Ky., 1906; member of the Mississippi State Medical Association; president of the county board of supervisors; aged 57; died, June 20, of brain tumor.

Wilber Price Armstrong Sr., Springfield, Ill.; Homeopathic Hospital College, Cleveland, 1884; member of the Illinois State Medical Society; aged 79; died, July 7, of pulmonary edema, diabetes mellitus and arteriosclerosis.

Joseph Adrian Stefanski, Chicago; Hering Medical College, Chicago, 1909; member of the Illinois State Medical Society; on the staff of the South Chicago Community Hospital; aged 55; died, July 3, of pneumonia.

Titus Samuel Lapp ☉ Waynesville, Ill.; Northwestern University Medical School, Chicago, 1931; aged 39; died, July 11, in the Deaconess Hospital, Lincoln, of a gunshot wound received when he was cleaning his gun.

Philip H. Feigen, Chicago; Chicago College of Medicine and Surgery, 1907; aged 67; on the staffs of St. Mary of Nazareth Hospital and the Michael Reese Hospital, where he died, July 25, of coronary thrombosis.

Charles J. Jamieson, Winnipeg, Man., Canada; McGill University Faculty of Medicine, Montreal, Que., 1879; aged 86; died, June 27, in the Winnipeg General Hospital of diabetes mellitus and arteriosclerosis.

Isaac Ernest Van Hoesen ☉ Coxsackie, N. Y.; Albany (N. Y.) Medical College, 1903; formerly health officer and county coroner; aged 58; died, July 10, of bronchogenic carcinoma of the left lung.

Boudinot Stimson, New York; Columbia University College of Physicians and Surgeons, New York, 1938; aged 43; resident physician at St. Luke's Hospital, where he died, June 28, of intestinal obstruction.

Frank W. Brey, Wabasso, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1910; member of the Minnesota State Medical Association; aged 54; died, June 8, of brain tumor.

Hiram Delaney Burns, Albert Lea, Minn.; University of Nebraska College of Medicine, Omaha, 1914; member of the Minnesota State Medical Association; aged 51; died, June 19, of coronary occlusion.

Ralph Ernest Dawson, Blanchard, Mich.; Detroit College of Medicine, 1906; member of the Michigan State Medical Society; served during the World War; aged 58; was found dead in bed, June 27.

Floyd James Malloy, Anaconda, Mont.; Creighton University School of Medicine, Omaha, 1928; member of the Medical Association of Montana; aged 37; died, July 8, of coronary embolism.

Thomas E. P. Chambers, Cleveland, Tenn.; Chattanooga Medical College, 1896; veteran of the Spanish-American and World wars; county physician; aged 67; died, July 18, of coronary thrombosis.

Robert T. Grime, Philadelphia; Jefferson Medical College of Philadelphia, 1892; member of the Medical Society of the State of Pennsylvania; aged 80; died, July 5, in the Presbyterian Hospital.

Malcolm Dean Miller, Akron, Ohio; Harvard Medical School, Boston, 1905; formerly head of the contagious disease division of the city health department; aged 61; was shot and killed, July 5.

Philip C. Giltner, Maunie, Ill.; University of Louisville (Ky.) Medical Department, 1889; member of the Illinois State Medical Society; aged 73; died, June 27, of a self-inflicted bullet wound.

Francis Joseph Delaney, Port Townsend, Wash.; John A. Creighton Medical College, Omaha, 1905; served during the World War; city and county health officer; aged 61; died, June 10.

Joseph Danly Budd, Kansas City, Mo.; St. Paul Medical College, 1887; at one time member of the state legislature of Minnesota; Civil War veteran; aged 92; died, July 21, of mitral stenosis.

Augustus Ralf Reder ☉ Aurora, Ill.; Washington University School of Medicine, St. Louis, 1894; aged 68; died, July 9, in Hot Springs National Park, Ark., of carcinoma of the liver.

Joseph T. Berry, Cincinnati; Eclectic Medical Institute, Cincinnati, 1883; aged 78; died, July 18, in the Bethesda Hospital of acute cardiac dilatation and carcinoma of the sigmoid.

Ferdinand P. Fisch ☉ Portland, Ore.; University of Oregon Medical School, Portland, 1906; aged 64; died, June 30, of ruptured diverticulum with peritonitis and bronchopneumonia.

Frederick Philip Lowenstein, Springfield, Mass.; University of the City of New York Medical Department, 1895; aged 65; died, July 13, of heart disease and arteriosclerosis.

John Bruyere, Trenton, N. J.; Jefferson Medical College of Philadelphia, 1884; member of the Medical Society of New Jersey; aged 81; died, June 24, of cerebral hemorrhage.

Rolla D. Pope, Long Beach, Calif.; Columbian University Medical Department, Washington, D. C., 1897; aged 70; died, June 26, of coronary occlusion and chronic myocarditis.

Vratislas J. Plhak, Detroit; Detroit College of Medicine and Surgery, 1915; aged 49; died, July 16, in the Harper Hospital of portal cirrhosis and cardiac decompensation.

Norborne Page Cocke ☉ Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1900; aged 62; died, June 29, of coronary thrombosis.

Alexander L. Martin Sr., Richmond, Va.; Medical College of Virginia, Richmond, 1895; aged 71; died, June 24, of uremia, chronic nephritis and arteriosclerosis.

John Chason, Chatom, Ala.; Louisville (Ky.) Medical College, 1905; at one time health officer of Baldwin County; aged 64; died, June 26, of biliary cirrhosis.

George Upton Bennett, Cleveland; Western Reserve University Medical Department, Cleveland, 1889; aged 81; died, July 8, of prostatic abscess and uremia.

Carl William Ulfert, Wheeling, W. Va.; College of Physicians and Surgeons, Baltimore, 1904; for many years county jail physician; aged 58; died, June 30.

George William Bock, St. Louis; St. Louis College of Physicians and Surgeons, 1886; aged 84; died, July 22, in the Lutheran Hospital of arteriosclerosis.

Alice Genevieve Blackadder Merchant, El Paso, Texas; Eclectic Medical College of the City of New York, 1891; aged 80; died, June 1, of arteriosclerosis.

John W. L. Cooper, Chattanooga, Tenn.; Tennessee Medical College, Knoxville, 1901; formerly health officer; aged 61; died, July 24, of cerebral hemorrhage.

John Edward Auchmuty ☉ Tamaqua, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; aged 55; died, June 18, in Buffalo.

Hubbard C. Wait, Etta, Miss.; Memphis (Tenn.) Hospital Medical College, 1903; veteran of the Spanish-American War; aged 64; died, June 18.

Oscar McLaughlin, Jackson, Ohio; Columbus Medical College, 1891; member of the Ohio State Medical Association; aged 74; died, June 30.

John Dustin Pollard, Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1915; aged 70; died, June 23, in Lake Geneva, Wis.

Thomas F. Jones, Denver; College of Physicians and Surgeons, Keokuk, Iowa, 1883; aged 85; died, June 25, in the Good Samaritan Hospital.

Arthur Edwin Darling ☉ Lynn, Mass.; Harvard Medical School, Boston, 1906; served during the World War; aged 61; died, June 19.

Arthur Stirling Gorrell, Regina, Sask., Canada; McGill University Faculty of Medicine, Montreal, Que., 1890; aged 70; died, June 3.

John Davis Robinson, Waller, Texas; Atlanta (Ga.) Medical College, 1889; aged 78; died, June 14, of cerebral thrombosis.

Joshua R. McCally, Dayton, Ohio; Eclectic Medical Institute, Cincinnati, 1890; aged 76; died, July 8, of cerebral hemorrhage.

Mary A. Baron Monroe, Wheeling, W. Va.; Eclectic Medical Institute, Cincinnati, 1889; aged 83; died, June 27.

Jesse J. Wells, Glass, Tenn.; University of Louisville (Ky.) Medical Department, 1880; aged 83; died, June 29.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D. D. N. J., cosmetics C. N. J., and foods F. N. J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Anthel Tablets.—Anthel Co., Philadelphia. Composition: aminopyrine and sal ethyl carbonate. For prevention of periodic pain and relief of arthritis, neuritis, rheumatism, toothache and some other things. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 15; May 1940.]

B. B. Headache Powders.—Specialty Sales Co., Atlanta, Ga. Composition: acetanilid, aspirin, caffeine and potassium bromide. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 4; May 1940.]

B. C. Headache Powders.—B. C. Remedy Co., Durham, N. C. Composition: essentially acetanilid, aspirin, caffeine, and potassium bromide. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 1; May 1940.]

Booth's Cough and Cold Remedy.—J. F. Booth, Harbor Springs, Mich. Composition: essentially small amounts of extracts of plant material, ammonium chloride and menthol with sugar, alcohol and water. Falsely represented as a remedy for coughs and colds, consumption, bronchitis and all inflamed conditions of the lungs and bronchial tubes.—[D. D. N. J., F. D. C. 96; May 1940.]

Cachets Algocratine.—E. Lancosme, Paris, France. Composition: acetophenetidin, aminopyrine and a small amount of caffeine. Pain killer. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 12; May 1940.]

Causalin.—Amfre Drug Co., New York. Composition: tablets and capsules containing aminopyrine, salicylic ethyl ester carbonate and a sulfonate such as quinolinesulfonate. For arthritis. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 8, 9 and 76; May 1940.]

Clidie Comfort Compound.—Hy'ne Co., Chicago. Composition: aminopyrine. Pain killer. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 13; May 1940.]

Daily Vitamins.—Daily Vitamins, Inc., Cincinnati. Composition: not more than 10 international units of vitamin B₁ per capsule, whereas product was represented to contain 200 such units.—[D. D. N. J., F. D. C. 75; May 1940.]

Dixie Fever and Pain Powder.—Swamp & Dixie Laboratories, Inc., Fort Smith, Ark. Composition: acetanilid, caffeine, baking soda and charcoal. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 6; May 1940.]

Dunwoody's Turpentine Emulsion.—Sam Swidler, Chicago. Composition: essentially mineral oil, a small amount of turpentine, traces of hypophosphites, an arsenic compound, quinine alkaloid, an organic iodine compound, glycerin and water. Falsely represented as a remedy for bronchial trouble, as a health builder and system purifier and as a remedy for malaria, typhoid and other wasting fevers, pneumonia, la grippe and influenza.—[D. D. N. J., F. D. C. 45; May 1940.]

Eau Sublime Instantaneous Hair Coloring.—Guilmard Co., Inc., New York. Composition included paraphenylenediamine. Declared potentially injurious if used as directed.—[C. N. J., F. D. C. 13; May 1940.]

E E Powders.—E E Medicine Co., Greenville, S. C. Composition: acetanilid, 4.99 grains per powder, aspirin and potassium bromide. For simple headache, neuralgia, muscular pains, head colds and fever. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 7; May 1940.]

Goody's Headache Powder.—Goody's, Inc., Winston-Salem, N. C. Composition: acetanilid, aspirin, caffeine and potassium bromide. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 3; May 1940.]

Hartshorn's Headache Powders.—E. Hartshorn & Sons, Inc., Northampton, Mass. Composition: essentially acetanilid, caffeine, baking soda and flavoring materials. For simple headache, sleeplessness, nervousness and colds. Dangerous to health if used as directed.—[D. D. N. J., F. D. C. 79; May 1940.]

Hed Klear.—Van Patten Pharmaceutical Co., Chicago. Nasal vaporizer. Accessory medicament, "Hed Klear Essence" was a mixture of volatile oils (including eucalyptus and menthol) with alcohol, acetone and water. Dangerous to health when used as directed.—[D. D. N. J., F. D. C. 39; May 1940.]

Hed-Lyte.—Hed-Lyte Co., Dallas, Texas. Composition: acetanilid, sodium bromide and caffeine. To relieve pain in simple headaches, simple neuralgia, muscular aches and pains; for feverish conditions due to colds and for nervousness due to excesses; for menstrual pains and for headache following alcohol or tobacco excesses. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 5; May 1940.]

Loris Permanent Lash and Brow Colure.—Loris Laboratories, Chicago. Composition included paraphenylenediamine. Declared potentially injurious if used as directed.—[C. N. J., F. D. C. 5 and 6; May 1940.]

Madam C. J. Walker's Tan-Off.—Madam C. J. Walker Manufacturing Co., Indianapolis. Contained ammoniated mercury. For freckles and skin blotches and for brightening sallow and dark skin. Declared potentially injurious if used as directed.—[C. N. J., F. D. C. 17 and D. D. N. J., F. D. C. 67; May 1940.]

Nazoscope.—Murray Laboratories, San Francisco, Santa Monica and Pacific Palisades, Calif. Nasal vaporizer. Accessory medicament, "Nazone," consisted essentially of volatile oils (including spearmint) with alcohol and water. Dangerous to health when used as directed.—[D. D. N. J., F. D. C. 40; May 1940.]

O. B. C. Capsules.—Thyrole Products Co. and Frank & Black, Philadelphia. Composition included thyroid and phenolphthalein. For obesity. Dangerous to health when used as directed.—[D. D. N. J., F. D. C. 41; May 1940.]

O. J.'s Beauty Lotion.—O. J.'s Beauty Lotion Co., Shreveport, La. Composition included corrosive sublimate. For removing pimples, freckles, tan and sunburn. Declared potentially injurious if used as directed.—[C. N. J., F. D. C. 19 and D. D. N. J., F. D. C. 72; May 1940.]

Othine.—Othine Laboratories, Inc., Buffalo. Contained ammoniated mercury. Skin and freckle bleach. Declared potentially injurious if used as directed.—[C. N. J., F. D. C. 20 and D. D. N. J., F. D. C. 69; May 1940.]

Pate-O-Graph.—H. W. Gillespie, Baltimore, and Tohin & Snell, New York. Nasal vaporizer. Accessory medicament labeled "Patol" was approximately 80 per cent of volatile oils (chiefly eucalyptus), approximately 20 per cent alcohol and a small amount of an ammonium compound. Dangerous to health when used as directed.—[D. D. N. J., F. D. C. 36; May 1940.]

Pen-E-Scope.—Pen-E-Scope Laboratories, Chicago. Nasal vaporizer. Accessory medicament consisted essentially of eucalyptus oil with small amounts of pine oil, camphor, menthol and acetone. Dangerous to health when used as directed.—[D. D. N. J., F. D. C. 37; May 1940.]

Peranol.—Peranol Products, Chicago. Nasal vaporizer. Accessory medicament, "Peranol Nasal Emollient" consisted of volatile oils including eucalyptus, camphor and menthol with approximately 19 per cent of alcohol. Dangerous to health when used as directed.—[D. D. N. J., F. D. C. 38; May 1940.]

Posner's Black Instantaneous Hair Coloring.—I. Posner, New York. Composition included paraphenylenediamine. Declared potentially injurious if used as directed.—[C. N. J., F. D. C. 15; May 1940.]

Sodasal.—Sodasal Laboratories, Detroit. Composition: aminopyrine, sodium salicylate, compounds of magnesium and calcium, citrates and carbonates, sugar and water. For rheumatic and other pains. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 18, 19 and 78; May 1940.]

Soule's External Lotion.—L. M. Brock & Co., Lynn, Mass. Contained corrosive sublimate. For removing tan, freckles and pimples. Declared potentially injurious if used as directed.—[C. N. J., F. D. C. 22 and D. D. N. J., F. D. C. 70; May 1940.]

Stanback Headache Powders.—Stanback Co., Salisbury, N. C. Composition: acetanilid, aspirin, caffeine, potassium bromide and a trace of baking soda. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 2; May 1940.]

Syn-O-Scope.—Syn-O-Scope Co., Inc., Chicago. Device for treating sinus trouble. Accessory medicament labeled "Synx Syn-O-Scope Refill" consisted of volatile oils such as eucalyptus and camphor with alcohol. Device declared dangerous to health when used as directed.—[D. D. N. J., F. D. C. 35; May 1940.]

Tablets Arbolone.—Arbolone Co., Dayton, Ohio. Composition: desiccated thyroid and extracts of plant drugs including an iodine-containing substance such as bladderwrack and a laxative drug such as cascara sagrada. For obesity. Dangerous to health when used as directed.—[D. D. N. J., F. D. C. 42; May 1940.]

VG-341.—O. E. Henspeter, Vining, Minn. Composition: essentially 94 per cent of sodium hydroxide, 3½ per cent of sodium carbonate and a trace of potassium carbonate. Misbranded because represented as an efficacious vapor gas treatment for hemorrhoids.—[D. D. N. J., F. D. C. 99; May 1940.]

Volz Anti-Rheumln.—Robert W. Brooks trading as the Volz Co., Erie, Pa. Composition: cinchophen, acetophenetidin, aspirin, lithium salicylate and cinchona bark. For rheumatic pain, muscular pain, muscular lumbago, simple headaches, simple neuralgia and gout. Declared potentially injurious if used as directed.—[D. D. N. J., F. D. C. 11; May 1940.]

PULMONARY EMBOLISM FOLLOWING INJECTION TREATMENT OF VARICOSE VEINS

To the Editor:—In my communication (*THE JOURNAL*, May 25, p. 2139) on the article by Dean and Dulin entitled "Pulmonary Embolism Following Injection Treatment of Varicose Veins" (April 6, p. 1344) I emphasized the need for the physician to get an impartial picture of the value or disadvantage of different methods in treating varicose veins. I called special attention to the statistics, which clearly indicate a much higher mortality among persons operated on than among persons treated by injection.

Dr. Harkins (July 20, p. 236) minimizes the impressive statistical figures by a strange interpretation "that case mortality must not be confused with treatment mortality," quoting Sicard and Gaugier, who gave an average of eight injections to a patient. Harkins follows: "Thus, if a patient survives one injection he still has to receive the other seven on the average before his final mortality rate can be computed, and by this time the mortality rate per case approaches that for ligation as given in the literature."

Such argument is misleading and does not help the unbiased reader to find the truth. According to Probst's report, quoted in my reply, "120,000 injections of varicose veins in 15,000 consecutive cases were observed by Sicard and Gaugier without a single mortality." In the very same paper Probst mentions the comprehensive statistics of McPheeters based on 53,000 injection cases and of Kettel on 60,000 injection cases.

LUDWIG ISAAK, M.D., New York.

FAVISM

To the Editor:—I am contriving some research work on a blood disease, "favism," on which many studies were made by my co-workers and myself in 1936. At that time I was professor of medicine at the University of Sassari, Italy, and I had an opportunity to observe many cases of this disease, as it is quite common on the Italian island of Sardinia. The interest in this disease is due not only to the suddenness of the attacks, to the resulting anemia and to the high death rate but also to the fact that complete clarification of its pathogenesis may cast light on the mechanism of hemolysis in general and of hemoglobinurias in particular.

Despite the fact that two cases were reported in volumes 101 and 109 of *THE JOURNAL* by McCrae and Ullery and by Hutton, the disease is not well known in the United States. It is possible that in some cities many cases occur but are not recognized because of the rarity of the condition. A prompt and correct diagnosis would permit the starting of a complete research plan, with a marked advantage not only for patients suffering with favism but also for patients suffering with other blood diseases.

The disease is caused either by ingestion of the seeds of the fava plant (synonyms fava beans, broad beans, jack beans) or by inhalation of the pollen of the same plant. The attack is accompanied by vascular disorders sometimes sufficient to cause collapse. It consists chiefly of a dangerous crisis of hemolysis followed by hemoglobinuria and jaundice and accompanied by fever and often diarrhea. The hemoglobinuria lasts for only a few days, but the picture may be prolonged by secondary anemia.

As the fava beans are a staple article of diet of people of Italian, Greek, Syrian and Egyptian descent residing in the United States, it is possible that attacks of favism occur every year, especially among children, and that cases are frequent in

sections of the country showing a preponderance of residents of the aforementioned foreign lands.

I would appreciate any letter directed to me by physicians in reference to their personal experience on this subject.

A careful observation of every case of jaundice may reveal new cases of favism and allow the starting of research leading to an advance of science in this field.

ALDO LUISADA, M.D.,
73 Martin Street,
Cambridge, Mass.

SAFE DRIVING AT NIGHT

To the Editor:—In the editorial "Safe Driving at Night" in *THE JOURNAL*, June 22, mention was made particularly of headlights and street lights. Although there has been tremendous visual improvement in night driving along these lines, little or nothing has been done about the misguiding and dangerous lights of private enterprise along the highway, particularly those of roadside stands and establishments. Their unshielded lights glaring in all directions frequently tend to misdirect the night driver, who with his more open road tends to speed. This combination of night driving, speed and distracting glare is a competent producing cause of accidents.

There ought to be a law requiring standardization of these dangerous sources of illumination so as to require their proper shielding and reflection in order that their rays will strike the establishments they advertise rather than blind the night driver.

The improved "sealed beam" headlight and modern highway illumination, such as with properly reflected "daylight lamps" (gas filled sodium vapor or neon and the better filaments) as well as reflecting guideposts, will not mean so much where there are disturbing, distracting light glares from privately owned establishments.

It would serve the roadside business man more to have his place illuminated and the night driver better to have his road properly shielded from such lights. Inexpensive shields and reflectors would readily do the trick. Systematic regulation is therefore required not only for the headlights and the highway lights but also for the illumination of private enterprise.

The misguiding lights of the roadside stand should not conflict with the guiding lights of the highway.

WILLIAM L. GOULD, M.D., Albany, N. Y.

"SARCOIDOSIS"

To the Editor:—The editorial on "Sarcoidosis" which appeared in the July 27 issue of *THE JOURNAL* interested us very much. The opening statement of the editorial reads: "Medical literature, particularly during the past four years, reveals a renewed interest in this disease of many eponyms."

It is interesting to note that in a comprehensive article on Boeck's sarcoid which we published in the *Archives of Internal Medicine* (44:721 [Nov.] 1929) we stated in our comment: "It is reasonable to assume from our study that neither the existence nor the significance of the syndrome is as yet appreciated by internists. But, from the perusal of the literature and from the observation of patients with this condition at clinics and at dermatologic clinical conferences, it is evident that the malady is not uncommon."

Our patient, a white man aged 52, had sarcoid lesions in the ears, on the eyelids, on the face and on the trunk. He complained of weakness, cough and hemoptysis. Bilateral hydrothorax was also present, and a total of 4,585 cc. of pleural fluid was removed from the right pleural cavity and 4,955 cc. from the left side on several aspirations. The pleural fluid yielded a positive Wassermann reaction, as did the patient's blood.

At postmortem examination, sarcoid lesions similar to those found on the skin were found in the epicardium, bronchial mucosa and mucosa of the ileum. Sections of tissue stained for bacteria (including the tubercle bacillus) revealed none. The diagnosis of Boeck's sarcoid was confirmed by histologic studies of the lesions.

At the time of the publication of our paper we concluded that "Boeck's sarcoid is an inflammatory, chronic infectious granuloma. The rational etiologic attitude to assume toward this condition is that it is caused by syphilis as well as by tuberculosis." Our contention that Boeck's sarcoid could be caused by syphilis is based on the clinical, histologic and post-mortem study of our patient.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

OSTEOPOROSIS

To the Editor:—A woman aged 61 has roentgenograms which show a definite postmenopausal osteoporosis. Besides, some of the other vertebrae show definite arthritic changes. She complains of pain in and around the left shoulder, in the chest and in the back. She also has a large gallbladder with a large solitary stone; however, the organ functions perfectly well, as is shown by the dye administration at the time the patient was roentgenographed. There is spasticity of the gastrointestinal tract, especially the large bowel, with several discrete diverticula in the region of the sigmoid. There is some enlargement of the cardiac image to the left of the midline, especially in the region of the ventricles. Blood examination is essentially negative. Fasting blood sugar is 114, nonprotein nitrogen 35, cholesterol 384. The Hinton and Kohn reactions are negative. The basal metabolic rate is plus 3. The left ventricle is dilated and hypertrophied, the aorta slightly widened. The hilar region is moderately increased in width and density. The electrocardiogram shows normal rhythm, rate 60, left axis deviation, inverted T's. The patient has a generalized obliterative and arteriosclerotic process throughout, especially in the lower extremities. The dorsalis pedis and posterior tibial pulsations are absent. Genito-urinary and gynecologic examinations by the local specialist brought negative results. For about three months the patient has complained of terrific pain in the lower part of the abdomen. She describes them as "menstrual" pains. Since the many examinations have proved negative, I came to the conclusion that these abdominal pains may be a continuation of the obliterative and arteriosclerotic process; and that some of the vessels of the mesentery or some vessels near the descending aorta became involved. Under frequent and small doses of glyceryl trinitrate these pains have subsided. For her osteoporosis I am giving the patient intramuscular injections of theolol. The thing I am interested most in at this time is the mode of treatment of the osteoporosis. In addition to the theolol I wish to give the patient some calcium. Just in what form, how much, how often and how long are the theolol and calcium to be administered? Is there any specific treatment for osteoporosis? For the obliterative condition the patient is using the latest machine recommended by Dr. Seibert with apparent good results. There is also a mild colitis for which a smooth diet, belladonna and a colloidal suspension of aluminum hydroxide is given.

M.D., Connecticut.

ANSWER:—Osteoporosis in a patient 61 years of age is exceedingly common. It has been suggested that demineralization of the human skeleton, often associated with pain in the weight bearing joints, with or without x-ray evidence of arthritic articular changes, is a normal condition of age quite comparable to gray hair. The fact that some patients show little or no loss of the mineral salts from the bones, however, would indicate that it is not entirely necessary with advancing years.

This osteoporosis may be produced as a result of diet which for many years is intermittently inadequate in its calcium content or as a result of faulty absorption of the minerals contained in the food, even though the diet may be adequate in these elements. These factors may hold when there is a chronic inflammatory condition in the gastrointestinal tract, chronic achlorhydria or possibly extreme atrophy of the intestinal mucosa. It is probable that a diet which is deficient in vitamin D for a period of many years may also lead to a slow

loss of minerals from the bones. Adenoma or hyperplasia of the parathyroid glands may play a part. Other factors undoubtedly are concerned, but any one of these or a combination of the four might explain the situation in the case referred to.

There is no specific treatment for osteoporosis. Some success has resulted from the administration of vitamin D in the form of one of the more easily available concentrates, in addition to a diet which is rich in its calcium and phosphorus content. There is little scientific evidence to indicate that the addition of inorganic calcium salts is of any particular advantage. The average individual can store a maximum of only a few hundred milligrams of calcium in a day. It is quite possible to create a positive calcium balance with the storing of 0.5 Gm. of calcium or more a day without the addition of inorganic salts. There is also some danger of giving massive doses of calcium either by mouth or intravenously, particularly to patients who already have evidence of vascular disease. The reference to terrific pain in the lower part of the abdomen for three months' duration is suggestive of malignant neoplasm. Metastases of osteolytic tumors not infrequently produce a roentgenographic picture of generalized osteoporosis in which a definite tumor outline is difficult or impossible to demonstrate.

If there are other manifestations to support a diagnosis of adenoma of the parathyroid gland, the first therapeutic procedure should be an operation to remove this tumor.

OFFSET PRINTING SPRAY

To the Editor:—Can you give information on a spray solution made by the DeVilbiss Company "for the prevention of offsetting" (type DHOS). This spray is used in a large printing concern and is sprayed continuously on freshly printed sheets to prevent the fresh ink from soiling the bottom of the next or top sheet. When this spray dries a powder is deposited and accumulates on everything in the vicinity of the machine. Some of the employees of this concern have wondered whether there is any possible harm from contact or inhalation of this spray. Are there any harmful ingredients or any records of any allergy or other trouble caused by this particular spray?

William C. Stephenson Jr., M.D., Roanoke, Va.

ANSWER:—The DeVilbiss Company advises that the solid portion of this offset printing material is acacia. Acacia and cornstarch are each widely used for this purpose. Ordinarily these substances are suspended in a quick-drying alcohol. Numerous instances of asthma have appeared among printers exposed to this operation. Printers sensitized to starch are not disturbed by acacia, and vice versa. At the meeting of the American Public Health Association in Kansas City, Mo., in 1938 it was recommended that offset drying be accomplished by the rapid running of the wet sheet over a band of flame or other heated surface across the press. As stated in the query, the spray process favors the rapid dispersion of a fine and inhalable dust with every sheet printed. The disease that arises is genuinely occupational and at times wholly incapacitating for this form of printing.

HYPERCHROMIC ANEMIA IN BEAUTY PARLOR OPERATOR

To the Editor:—A patient has had anemia for eight years. She is 44 years old, is married, has had no pregnancies and is a beautician by trade. A complete physical examination reveals only some slight systolic tenderness over the right lower quadrant of the abdomen, a rough systolic murmur in the third left interspace adjacent to the sternum and a mild pyrrhea. She is somewhat overweight, of healthy appearance, has normal menstrual periods and complains only of some tiredness. The family history is negative for pernicious anemia but the patient's mother has diabetes. Blood tests reveal hemoglobin 11.6 Gm. (75.2 per cent), red cells 3,170,000, white cells 5,600, polymorphonuclear leukocytes 57 per cent, lymphocytes 41 per cent, eosinophils 2 per cent, blood sedimentation 49 mm. per hour (Wintrobe method), Wassermann reaction negative. Urinalysis is negative. Gastric analysis reveals a free acid of 28 and a total of 50. The stained smear reveals much variation in size and shape at the red cells, which are uniformly well filled with hemoglobin. The question which arises is as to the cause of the hyperchromic anemia. All foci have been checked. The patient has been treated with adequate doses of liver, iron and vitamin B₁₂, all without marked success. The count went above 3,600,000 on only two occasions. Is it possible that she might be allergic to some of the products used in beauty work with consequent depression of bone marrow hemopoietic activity?

M.D., Indiana.

ANSWER:—The blood picture is that of a mild hyperchromic anemia, the etiology of which is not clear. Pernicious anemia should be considered but is unlikely owing to the presence of free acid in the stomach and the lack of response to liver therapy. However, the patient may be suffering from so-called acrostatic anemia, which resembles pernicious anemia in every way except in its lack of response to liver therapy.

A chronic low-grade hemolytic process may be present in this case, for hemolytic anemia presents a similar blood picture.

Further examination of the blood is necessary, including a reticulocyte cell count, red cell fragility test and icteric index. The urine and stool should be examined for urobilin. No mention is made of an enlarged spleen. This is usually present in hemolytic anemia but is not evident in all cases.

It is also advised that a sternal puncture be done and the bone marrow examined. This is often of great diagnostic value. A hyperplastic bone marrow, with an increase in erythroid elements, will point to a hemolytic process affecting the peripheral red blood cells. A hypoplastic bone marrow will point to a depression of the erythroid elements in the marrow.

A not infrequent and often obscure cause for hyperchromic anemia is hypothyroidism. The symptoms of the latter may be mild. The basal metabolic rate should be determined, since the patient is overweight and complains of some fatigue.

The question concerning the relation between the anemia and the patient's occupation is an interesting one. Depression of the bone marrow or a hemolytic process resulting from hair dye, for example, has been observed in occasional cases but is rare. In such cases the preparation was frequently applied directly to the scalp. In this case, however, it is unlikely that exposure to the products handled by the patient is a factor in the anemia. Nevertheless, because of the persistence of the anemia, it would perhaps be advisable for the patient to stay away from her occupation for several weeks to determine whether any improvement occurs.

Since prolonged treatment with iron, liver and vitamin B₁ has been of no avail, blood transfusion may be indicated. After one or two transfusions the effect on the blood picture should be determined. Finally, it must be kept in mind that the patient may be suffering from a refractory anemia of unknown etiology, instances of which have been reported by Rhoads. Treatment in such cases is of no avail.

ARTERIOSCLEROSIS, INJURY, VASCULAR SYPHILIS AND CEREBRAL THROMBOSIS

To the Editor:—A blacksmith aged 59, with noncontributory personal and family history and in good general health, while carrying a heavy round iron in his left hand caught the cuff of his right pant leg on a pipe and fell to the ground. In falling he cast the round iron from him and landed on his right hip and hand; except for the momentary jor and a skinned place on his right ankle there was no apparent disturbance from the fall. Four or five hours later, about two hours after he had gone to bed, he woke up cold and noticed that his right leg was "jittering" and that he could not hold it still. During the following four days this "jittering" in the right leg continued and by the second day he noticed that he dropped his hammer rather frequently and that his right arm had also become "jittery." On examination at this time he was found to be mentally somewhat excitable and there were almost constant and continuous choreiform movements of the right arm and right leg. These movements seemed to start from the shoulder and hip and were uncontrollable by the patient. There was no pain, no muscle spasm, no disturbance of skin sensation, and no observable change in deep or superficial reflexes. Other than the mental disturbance and movements there were no physical or neurologic abnormalities. The blood Wassermann reaction was positive; the spinal Wassermann test and gold curve were negative. He was considered to have a central nervous system siphylis with beginning degeneration. He was treated with intravenous arsenicals and intramuscular bismuth compounds and during the following year and a half has gradually improved both mentally and physically. He is now mentally alert, cooperative, of good memory for persons, places and events, and seemingly in his usual mental condition. The choreic movements are quite moderate and voluntarily controllable for short periods of time. Neurologic examination is negative except for the movements. There is no atrophy in the affected members. The eye-grounds show sclerosis of the retinal vessels. The systolic blood pressure has been from 130 to 140 throughout. The blood Wassermann and Kahn reactions have continued positive on six examinations made at intervals during this period and in three different laboratories. Spinal fluid tests at the same intervals have been consistently negative (including Wassermann, colloidal gold and globulin tests and cell counts). Two spinal fluid tests were made before treatment was started. What would be the likelihood of an active central nervous system siphylis with a constantly normal spinal fluid? Is it at all possible that a fall such as he had could cause a cerebral hemorrhage in some motor tract and account for the hemichorea? Would not the time interval of four and one-half to five hours following the jar be too long for such a theory? The patient has no previous knowledge of siphylis, and treatment has made no impression on his blood Wassermann reaction. Is it possible to have a constantly positive blood Wassermann reaction without siphylis? Would you advise continuation of active siphylitic treatment? Have you any other suggestions for diagnosis or treatment?

Ralph F. Palmer, M.D., Phoenix, Ariz.

ANSWER:—The fall of a man who was somewhat arteriosclerotic, as shown by later examination of the retinal vessels, and was also 59 years old and suffering from vascular siphylis, in all probability gave rise to a cerebral thrombosis. Unlike the usual cerebral thrombosis resulting in a hemiplegia, this lesion, probably in the left corpus striatum, produced a condition of hemichorea. There is experimental and clinical evidence suggesting that lesions of the caudate nucleus and the putamen of

the corpus striatum will cause choreiform movements, although it is also known that lesions in other masses of gray matter in the basal ganglion will be made evident by chorea or other involuntary movements. The lesions of chorea are thus not sharply localized, but in the case presented exact localization is not particularly important.

The onset, course and residual symptoms are consistent with cerebral thrombosis. The accident may be labeled as a secondary cause, in spite of the fact that no cerebral trauma is known to have taken place. Is the thrombosis on the basis of arteriosclerosis or siphylitic endarteritis? One cannot be sure. The latter seems most likely, as there is no evidence of hypertension; the man's age may account for the amount of retinal sclerosis found, and some recovery has taken place under antisyphilitic treatment. There is no evidence that the man ever had more than vascular siphylis. The central nervous system was never involved, except by the chance of a cerebral artery being the seat of the endarteritis, and examination of the cerebrospinal fluid was repeatedly negative. Central nervous system siphylis with a completely negative cerebrospinal fluid—cells, globulin, colloidal gold test and Wassermann test—is not considered possible, except as an end result for a thoroughly treated patient. Cerebral hemorrhage seems less likely than thrombosis, particularly if the cerebrospinal fluid was negative at the start of the disease. An interval of from four and one-half to five hours after the accident would be more consistent, moreover, with thrombosis than hemorrhage. The presence of repeatedly positive blood Wassermann tests, before and after treatment, strongly suggests siphylis.

It would appear that thorough treatment had been carried out. The residual chorea must be considered as the permanent after-effect of the thrombosis. Continued treatment of a man who has made a good if not complete recovery, both mentally and physically, is not advised. He should be examined by a physician, preferably one who is familiar with the details of his past history and treatment, twice a year and the cerebrospinal fluid should be examined once a year. If changes occur, treatment must be guided by those changes. Many physicians treat patients who have this type of history at least once a year with short courses of bismuth compounds, six to eight injections, regardless of the tests. Such a procedure has much to recommend it; patients with long-standing siphylis are often kept at a high level of health and recurrences are probably prevented by some treatment every year. This type of siphylis is never "cured" in the sense of complete eradication. The patient may be cured of his symptoms, however, and remain so.

HERNIATION THROUGH MESENTERY

To the Editor:—I have just encountered an anomaly in the abdomen which I have never seen and of which I have never heard. In opening an abdomen presenting acute symptoms, I found about 6 feet of gangrenous jejunum and ileum herniated through an opening in the base of the mesentery of the jejunum. Strangely a loop of jejunum had passed through from one side and a loop of ileum from the opposite side in apposing directions, and both were completely gangrenous. This aperture was not that formed by the ligament of Treitz but directly through and through the mesentery. I resected all gangrenous intestine and did a side to side anastomosis, leaving about 12 inches of intestine below the stomach. How frequently has this condition been found and what have been the operative results? What also have been the operative results of herniation through the inferior duodenal fossa, which results should compare in some manner with what I might expect? This patient has never been nauseated, either before or after surgery, and was ill only fourteen hours before operation. Her postoperative condition is satisfactory after eighteen hours. Have you any suggestion concerning her digestive management immediately following operation or later, if such the case may be?

H. R. Wilber, M.D., Jeffersonville, Ind.

ANSWER:—Hansmann and Morton (*Arch. Surg.* 39:973 [Dec.] 1939) report a fatal case of herniation of the cecum through a hole in the mesentery of the small bowel. These authors studied 467 cases of internal hernia collected from the literature and found that sixty involved the transverse mesocolon and that thirty-eight were mesenteric. Hernia of the transverse mesocolon was commoner in women but intra-abdominal hernias, as a whole, were commoner in men. Mitchell (*Ann. Surg.* 30:505, 1899, quoted by Watson) found holes in the mesentery of three subjects in 1,600 necropsies. Treves (*Intestinal Obstruction*, London, Cassell & Co., Ltd., 1899, p. 65, quoted by McIver) said that the openings are most frequently found in the mesentery of the lower portion of the ileum and may be traced to abdominal injury. Watson (*Ann. Surg.* 106:1097 [Dec.] 1937) says that up to 1937 only thirty-seven cases of intestinal obstruction due to defect in the mesentery had been reported. Watson reported an additional case in which nearly the entire lower portion of the ileum was herniated through a hole in its mesentery about 6 cm. proximal to the ileocecal valve. His patient

recovered after operation. Edwards (*THE JOURNAL*, July 23, 1932, p. 278, quoted by Watson) found eleven recoveries in thirteen cases in which reduction was effected and four recoveries in eight cases in which resection was necessary. (See also Cutler, G. D.: Mesenteric Defects as a Cause of Intestinal Obstruction, *Boston M. & S. J.* 192:305 [Feb. 12] 1925; Bona, T.: *Zentralbl. f. Chir.* 65:144 [Jan. 15] 1938; Baty, J. A.: *Brit. M. J.* 1:671 [March 26] 1938; Smith, A. M.: *Ann. Surg.* 96:292 [Aug.] 1932; Menegaux, G.: *J. de chir.* 43:32 [March] 1934.)

As soon as fluids are tolerated by mouth, these may be gradually increased and after three or four days a residue-free diet may be employed. A soft diet may be given at about the seventh to the tenth day and a general diet by the fifteenth day.

VASODILATATION PHENOMENON AFTER NICOTINIC ACID

To the Editor:—Four weeks ago a postmenopausal, somewhat neurotic woman had a dry, scaling dermatitis. In conjunction with local treatment, I prescribed nicotinic acid 50 mg. three times a day. After taking the first tablet with half a glass of water the patient telephoned me that she was having severe "hot flashes" and felt weak and dizzy. This lasted for perhaps fifteen to fifty minutes. Two days later I again persuaded her to take the nicotinic acid tablets. Again she felt hot and flushed over the face, scalp and neck and complained of weakness and vertigo. The dose was cut to 25 mg. four times a day and the patient tolerated the drug thenceforth. Last week I again prescribed nicotinic acid three times a day to a man aged 50. He also noticed similar flushes of the face, warmth and some vertigo. After reassurance he again took the tablets and had two mild attacks, followed by another severe one and then developed cheilitis. Are there any similar reports of sensitivity to nicotinic acid? I at first dismissed the first patient's complaint as being psychogenic in origin until the second, of more stable personality, experienced a similar disturbance. Joseph C. Anderson, M.D., Ebensburg, Pa.

ANSWER.—The reactions described are probably due to a vasodilatation phenomenon which usually occurs when nicotinic acid is administered orally in doses of from 50 to 100 mg. or intravenously in doses of 10 mg. These reactions are transitory and, although unpleasant, are harmless (Spies, T. D.; Bean, W. B., and Stone, R. E.: *The Treatment of Subclinical and Classic Pellagra*, *THE JOURNAL*, Aug. 13, 1938, p. 584). They are described in more detail by W. B. Bean and T. D. Spies in a publication which will appear in the *American Heart Journal*. The dizziness and vertigo occur in a certain number of cases. The cheilitis, or chloicosis, appears frequently in individuals who are on a poor diet even though they are taking nicotinic acid. The cheilitis is a result of a deficiency of riboflavin in the diet and not of nicotinic acid, and it disappears following the administration of from 3 to 5 mg. of riboflavin daily for a week.

DISSECTING ANEURYSMS

To the Editor:—A white man aged 60 died of hemopericardium secondary to rupture of a dissecting aneurysm of the ascending portion of the aortic arch. A blood Wassermann test gave negative results. What are the etiologic possibilities? There were no apparent symptoms until a few days before death, when the patient underwent some unusual muscular effort. Could this have caused a fracture of the intima with resulting aneurysm? Could an injury (severe bodily injury with probably some squeezing of the chest) sustained some eight or nine years ago have caused a dissecting aneurysm which remained quiescent all those years? M.D., Pennsylvania.

ANSWER.—Dissecting aneurysms, when clearly of traumatic origin, are more commonly seen in the transverse and descending portions of the aortic arch than in the ascending portion. The location of this lesion suggests that the aorta might well have been previously damaged by syphilis, in spite of the negative blood Wassermann reactions. A microscopic study of the aorta, presumably possible from the accurate description of the gross observations given, would help to determine the specific etiology in this case. A relatively small percentage of cases of aneurysm of the aorta are caused by trauma. Among those so caused, dissecting aneurysms are relatively frequent and some of these patients may survive for ten or more years after the onset without symptoms. The type of injury most commonly associated with the development of a dissecting aneurysm is one involving a fall on an object which strikes a fairly localized portion of the chest wall or an accident involving squeezing of the chest. There is a difference of opinion about the effect of unusual muscular effort on the development of hemorrhages from the vasa vasorum, which in turn might injure the intima sufficiently to cause rupture of it or thrombosis over the injured area. The unusual muscular effort might well have led to a further extension of the dissecting aneurysm, which ultimately ruptured into the pericardium. Whether the muscular effort alone could have caused a sufficient dilatation of the aorta under increased pressure in a way that resulted in the original rupture

of the intima is problematic but not impossible, especially in the presence of what might be regarded as normal changes in the aorta of a man of 60.

LONG-CONTINUED ADMINISTRATION OF PHENOBARBITAL

To the Editor:—For how long may one take thirty drops of elixir of phenobarbital three times a day? A patient has been taking this amount for six months with no apparent bad effect. It has been suggested that she discontinue the drug, but her referring physician says that she need not stop as it will produce no harm. This is not a controversial matter, but what is best for the patient?

Leon J. Menville, M.D., and Joseph N. Ane, M.D., New Orleans.

ANSWER.—The barbiturates which contain unsaturated chemical groups in the molecule are largely broken down in the liver, and usually their action is not long in duration. Those which contain saturated groups do not undergo metabolism and are excreted, largely unchanged, by the kidneys. Their action is much longer continued. If the liver is functioning properly, the first mentioned group of barbiturates are disposed of promptly. A damaged liver probably could not destroy them. If the kidneys are functioning properly, the saturated barbiturates are excreted.

Phenobarbital is a saturated barbiturate. The elixir of phenobarbital contains 0.4 per cent of the drug. The patient in question is receiving 0.008 Gm. (one eighth grain) of phenobarbital three times daily. This is one fourth of the U. S. P. dose. Many individuals appear to suffer no harmful effects following long-continued intake of barbiturates, but others may acquire addiction even with small dosage. It is always wise to discontinue a drug when possible, as its cumulative effects can never be anticipated in an individual case.

SULFANILAMIDE POWDER

To the Editor:—There is some question as to whether it is safe to use sulfanilamide powder, unless first autoclaved in open wounds. What is the possibility of this drug containing tetanus spores when secured by pharmaceutical houses and what chemical changes are produced by autoclaving?

Fred F. Davis, M.D., Roanoke, Va.

ANSWER.—As far as available reports go there have been no reactions or infections following the topical use of sulfanilamide powder. Crystalline sulfanilamide is hard to sterilize. The question as to whether the crystalline drug might possibly contain tetanus spores has not been raised previously, and as far as is known there are no reports on this point. There is also no information concerning the chemical changes which might take place if crystalline sulfanilamide is autoclaved. It is known that occasionally prolonged autoclaving of sulfanilamide solutions brings about an oxidation of the drug which gives rise to the formation of a discolored yellow or brown solution. Such discolored solutions or discolored crystalline sulfanilamide itself should never be used.

ALLERGIES AND HYDROCHLORIC ACID

To the Editor:—Kindly tell me the status of the intravenous use of hydrochloric acid in intestinal and other allergies.

Alfred Ellison, M.D., South Bend, Ind.

ANSWER.—There is no authentic literature at the present time supporting the use of intravenous hydrochloric acid in intestinal and other allergies. It is apparently a fad which was given up a long time ago and certainly it is not being utilized by the majority of allergists. Whatever virtue such therapy might have or might have had is probably based on the production of mild shock therapy, probably due to the hypotonicity of the fluid injected. There is no good evidence that this type of treatment deserves a place in the management of allergic diseases.

UNDESCENDED TESTIS AND MALIGNANCY

To the Editor:—A patient aged 38 has an occasional pain in the right testis, which is about half normal size. The testis is in the upper part of the scrotum and was put there twenty years ago in an operation for undescended testis. It has never grown. His sexual history is normal. What chance is there of this becoming malignant? Would you advise removal as a prophylactic against a possible malignant condition?

M.D., Texas.

ANSWER.—Although the best available statistics reveal that the percentage of malignancy in undescended testes is higher than in testes in the normal position, the removal of this testis as a prophylactic against possible malignancy would probably not be advisable. Since it has been in the upper part of the scrotum for the past twenty years, the possibility of its becoming malignant is no greater than it would be if it were a normal testis.

Medical Examinations and Licensure

COMING EXAMINATIONS

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, August 17, page 557.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Written*. Parts I and II, Sept. 11-13, to be given in medical centers having five or more candidates desiring to take the examination. Part III, Baltimore and New York during October and Boston during November. Excc. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various centers, Feb. 20. Final date for filing application is December 21. Orol. Cleveland, preceding A. M. A. convention. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Various centers, Oct. 28. Applications must be on file not later than Sept. 16. Orol. Chicago, Dec. 6-7. Applications for Group A must be on file not later than Nov. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. October 21. Applications must be on file not later than September 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Chicago, Oct. 18-19. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville, Ky.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I. Group B. Various centers, Jan. 4. Final date for filing application is Oct. 5. Part II. Groups A and B. Cleveland, preceding A. M. A. convention. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Orol. Cleveland, Oct. 5. *Written*. Various centers, March 8. *The only written examination during 1941*. Applications must be on file not later than Dec. 1. A special oral and clinical examination will be held on the Pacific Coast during 1941 providing there will be enough candidates to warrant it. Applications for this examination should be on file not later than Sept. 15. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Oral and written*. New Orleans, January 1941. Final date for filing application is November 15. Sec., Dr. Fremont A. Chaudler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PEDIATRICS: New York, March 30-31, following the Region I meeting of the American Academy of Pediatrics. Chicago, May 18, following the Region III meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Orol. New York, December 18-19. Final date for filing application is October 8. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Boston, Sept. 26-29. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written*. Part I. Various centers, October 21. Final date for filing application is September 15. Sec., Dr. J. Stewart Rodman, 225 S.

AMERICAN BOARD OF UROLOGY: Chicago, February 1941. Applications must be on file not later than Oct. 15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Minnesota April Report

Dr. Julian F. Du Bois, secretary, Minnesota State Board of Medical Examiners, reports the written examination for medical licensure held at Minneapolis, April 16-18, 1940. The examination covered twelve subjects and included sixty questions. An average of 75 per cent was required to pass. Forty-four candidates were examined, all of whom passed. Four physicians were licensed by reciprocity and four physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of California Medical School.....	(1939)	88.2	
Northwestern University Medical School.....	(1938)	87.1,	
87.5, 88.4, 88.8, (1939) 85.2, 89.5,* 90.5, 91.5*	(1938)	92.5	
Rush Medical College	(1939)	89	
University of Chicago, The School of Medicine.....	(1939)	96.1	
University of Illinois College of Medicine.....	(1936)	92.3	
State University of Iowa College of Medicine.....	(1938)	86	
University of Kansas School of Medicine.....	(1937)	90	
Tulane University of Louisiana School of Medicine.....	(1938)	89, 91.3	
Johns Hopkins University School of Medicine.....	(1937)	88.1	
University of Michigan Medical School.....	(1938)	90.5,	
University of Minnesota Medical School.....	(1938)	90.5,	
(1939) 82.6,* 86.3,* 86.4,* 86.6,* 87.2,* 88.8,* 89.3,	(1939)	86.2	
90,* 90.6, 91, 91.2,* 91.2,* (1940) 84.3,* 88.3,* 89.5	(1937)	87.3	
Creighton University School of Medicine.....	(1935)	89.1	
University of Nebraska College of Medicine.....	(1938)	86.1	
Columbia University College of Physicians and Surgeons.....	(1938)		
University of Rochester School of Medicine.....	(1938)		

Duke University School of Medicine.....	(1938)	85.6	
University of Oregon Medical School.....	(1939)	86.3	
University of Texas School of Medicine.....	(1928)	89.1	
University of Wisconsin Medical School.....	(1938) 89.6, (1939)	90.2	
McGill University Faculty of Medicine.....	(1937)	89.6	

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with

*This applicant has received the M.B. degree and will receive the M.D. degree on completion of internship.

Wyoming June Report

Dr. M. C. Keith, secretary, Wyoming State Board of Medical Examiners, reports the written examination for medical licensure, held at Cheyenne, June 3-4, 1940. The examination covered twelve subjects and included eighty-one questions. An average of 75 per cent was required to pass. Three candidates were examined, two of whom passed and one failed. One physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Oregon Medical School.....	(1939)	77.7	
University of Wisconsin Medical School.....	(1936)	75	

School	FAILED	Year Grad.	Number Failed
University of Nebraska College of Medicine.....	(1938)		1

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad.	of
Yale University School of Medicine.....	(1934) N. B. M. Ex.		

Missouri Reciprocity Report

Dr. Harry F. Parker, secretary, State Board of Health of Missouri, reports fourteen physicians licensed to practice medicine by reciprocity and one physician so licensed by endorsement. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Illinois College of Medicine.....	(1939)		Illinois
Rush Medical College.....	(1936)		Minnesota
University of Kansas School of Medicine (1934), (1936), (1938, 2), (1939, 4) Kansas			
Johns Hopkins University School of Medicine.....	(1935)		Maryland
Harvard Medical School	(1935)		Minnesota
University of Pennsylvania	(1935)		New York
University of Tennessee	(1938)		Tennessee

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad.	of
New York University College of Medicine.....	(1934) N. B. M. Ex.		

Utah June Report

Mr. G. V. Billings, director, Department of Registration, reports the written examination for medical licensure held at Salt Lake City, June 24, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Nine candidates were examined, all of whom passed. Fourteen physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School.....	(1940)	87, 88	
Rush Medical College.....	(1939) 82, 82, (1940)	86*	
University of Maryland School of Medicine and College of Physicians and Surgeons	(1940)	86*	
Creighton University School of Medicine.....	(1940)	87*	
Temple University School of Medicine.....	(1939)	84	
University of Pennsylvania School of Medicine.....	(1939)	85	

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Colorado School of Medicine.....	(1936), (1937)		Colorado
Rush Medical College.....	(1906) Washington, (1937)		Illinois

Maryland Homeopathic June Report

Dr. John A. Evans, secretary, Board of Medical Examiners of the State of Maryland (Homeopathic), reports the written examination for medical licensure held at Baltimore, June 18-19, 1940. The examination covered nine subjects and included 70 questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed. The following school was represented:

School	PASSED	Year Grad.	Per Cent
Hahnemann Medical College and Hospital of Philadelphia	(1939)		79,
81, 81, 81, 82, 82, 84, 85, 88, 88			

Massachusetts Endorsement Report

Dr. Stephen Rushmore, secretary, Massachusetts Board of Registration in Medicine, reports twenty-five physicians licensed to practice medicine by endorsement from January 4 through April 22. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad. of
College of Medical Evangelists.....	(1938)	N. B. M. Ex.
University of Colorado School of Medicine.....	(1938)	N. B. M. Ex.
University of Georgia School of Medicine.....	(1937)	N. B. M. Ex.

McGill University Faculty of Medicine.....	(1933)	N. B. M. Ex.

Oklahoma June Report

Dr. James D. Osborn Jr., secretary, Oklahoma State Board of Medical Examiners, reports the written examination for medical licensure held at Oklahoma City, June 5-6, 1940. The examination covered twelve subjects and included 120 questions. An average of 75 per cent was required to pass. Forty-seven candidates were examined, all of whom passed. Twenty-four physicians were licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Oklahoma School of Medicine.....	(1940)*		78.4,
79.3, 79.7, 80, 80.4, 80.5, 80.5, 80.7, 80.7, 81, 81, 81, 81.5, 81.8, 82, 82, 82, 82.5, 82.5, 82.5, 82.6, 83, 83, 83, 83.4, 83.4, 83.8, 84, 84, 84, 84.2, 84.5, 84.8, 84.8, 85, 85, 85.7, 85.9, 86, 86, 86.5, 86.7, 86.9, 87.6, 88, 89.4

Book Notices

Modern Medical Therapy in General Practice. Edited by David Preswick Barr, A.B., M.D., LL.D., Busch Professor of Medicine, Washington University, St. Louis. Volume I: General Therapy; Methods Used in Therapy; General Diseases. Volume II: Infectious Diseases; Diseases of the Nervous System; Diseases of the Digestive System. Volume III: Diseases of Other Organs and Systems; General Index. Cloth. Price, \$35, per set. Pn. 1200; 1203-2446; 2447-3661, with illustrations. Baltimore: Williams & Wilkins Company, 1940.

This has been a great year for systematic works on the treatment of disease. The volumes edited by Dr. Barr have a distinguished list of contributors who in themselves represent the technic of practice in more than fifty hospitals as well as teaching physicians in many medical schools. The membership of Dr. Barr on the Council on Pharmacy and Chemistry is assurance of the scientific point of view in evaluating therapeutic methods. In the introduction Dr. Barr thanks particularly Dr. Tracy J. Putnam for his contribution on the nervous system and for his aid in editing the other contributions in that field.

After an introductory chapter, which is largely a survey of the history of therapy and which concludes that there can no longer be the slightest excuse for an attitude of therapeutic nihilism, the work begins with a discussion of general methods in therapy including psychotherapy, the use of drugs, vaccines and serums, organotherapy, fluid administration, dietotherapy, physical therapy, balneotherapy, occupational therapy and miscellaneous procedures. This work would in itself constitute a first class single volume on the practical aspects of the treatment of disease. Each of the sections is supplemented by a good bibliography, so that the reader can trace the historical development of each technic. There are innumerable tables and charts providing data in succinct form, especially valuable being the food tables and those classifying sources of light.

Next comes the specialized discussion of various conditions such as diseases of metabolism, diseases of allergy, the deficiency diseases, the intoxications and diseases due to chemical agents. The writers have been chosen with regard primarily to their qualification rather than with regard to any geographic or similar distribution.

The second volume deals with the infectious diseases and those of the nervous and digestive systems, the third volume with diseases of other organs and systems. Each volume has a separate index and there is a general index in volume III covering the entire system. There are a considerable number of illustrations in the volumes and charts and diagrams, all of which are chosen primarily with a view to their great usefulness.

Thus there is now again available a modern consideration of various forms of treatment from men who are known to be qualified. The section on diseases of the ductless glands is itself prepared by a variety of specialists, indicating how highly technical has become the problem of medical care with the rapid advance of modern knowledge. The volumes in this work are numbered consecutively from the first. The books may be heartily recommended to all physicians who wish an up-to-date work as a constantly available reference on the office table.

Fundus Atlas: Stereoscopic Photographs of the Fundus Oculi. By Louis Bollman, B.S., M.D., F.A.C.S., Clinical Professor of Ophthalmology, the University of Chicago, Chicago, and Reuel W. Bennett, Photographer for the Division of Ophthalmology, the University of Chicago Clinics. Cloth covered case. Price, \$17. 50 (7 x 9 inch) cards with 50 original stereoscopic photographs. Chicago: Year Book Publishers, Inc., 1939.

The atlas presents just what the preface claims for it, namely some selected photographs of unusual or important conditions of the fundus. Unfortunately it is not comprehensive enough for a fundus atlas of reference nor is there enough detail or a sufficient number of illustrations to be used as a textbook for teaching. Many of the conditions pictured are most unusual, as for example the picture of opaque nerve fibers. A beginner, seeing this for the first time, would have difficulty recognizing the usual picture of a few strands above or below the disk. There is a question as to the interpretation of some of the photographs. No. 2 is described as a bowl shaped, physiologic excavation; it appears to the reviewer as a partial coloboma of the nerve head even though the vision is normal. The epipapillary membrane in chart 4 is correctly interpreted, but not the usual translucent veil seen over the disk. Neither is the persistent hyaloid at all typical. No. 9, picturing glaucomatous

excavation, does not show the vessels at the bottom of the disk. It would have been better had the camera been focused to show both the surface and disk bottom, even though the latter was not in exact focus. In No. 10 the title is not convincing. The papilledemas are splendid, but a series of photographs of this case in different stages would have been fine for instruction. No. 27, featuring preretinal hemorrhage, does not give the clear outline usually seen in this condition or the level top. The superior retinal vein and central vein thromboses are beautiful pictures. No. 33 reveals a most unusual type of traumatic, proliferating retinitis. No. 36 is a splendid representation of that rare condition retinitis punctata albicans. The types of choroiditis are representative, though it might have been better had No. 39 been supplemented with a picture showing the condition in its active stage. This might be said of No. 46 also, in which a later stage, showing the cherry red spot, would have added considerably to its value. The last photograph, showing detachment of the vitreous, is worth almost the price of the collection. Any one deeply interested in the study of fundus conditions will prize this collection of beautiful photographs. It is to be regretted that, with the large material at the disposal of the author, the skilful technical photography and with his long and excellent teaching experience, there was not a larger and more complete series of photographs presented, outlining, for example, the various stages of choked disk, the variations in the normal disk appearance and outlining detailed stages of retinal arteriosclerosis and the like. He would then have had an atlas that would be invaluable for teachers and for students of ophthalmology.

L'hématologie: Clinique et laboratoire. Par P. Emile Weil, médecin des hôpitaux de Paris. Paper. Price, \$3.25. Pp. 269, with 81 illustrations. Paris: Masson & Cie, 1939.

The author has intended this work to be a presentation of the laboratory procedures essential for the diagnosis and prognosis of diseases of the blood, as well as a cytologic and clinical description of the manifestations of such disorders. The first part of the book is devoted to such topics as the origin of blood cells, physical and chemical constitution of whole blood, enumeration of the formed elements of blood, study of stained and fresh blood, its morphology in normal and abnormal states, the fragility test and its value, blood grouping, sedimentation, coagulation, capillary fragility and sternal puncture. The common causes of the respective abnormalities are briefly mentioned. The author is incorrect in stating that the occasional case of sickle cell anemia seen in the white race is due to a mixture of Negro grandparent, for instances in which the Negro trait could be excluded have been recorded. The erythrocytic changes in malaria are too briefly described to be of much value, and absence of illustrations leaves much to be desired. The hematocrit, so important in the study of red cell volume, receives no mention; neither does the halometer. The author expresses a predilection for the Sahli hemometer, although he describes only the Gowers and Tallqvist hemometers. The chapters on sternal marrow puncture and on auto-agglutination are ably presented. However, to devote one chapter to the cytology of serous cavities and spinal fluid seems inappropriate for a book of this type. The second part of the book deals with a brief clinical and hematologic picture of the various blood diseases. Only the common forms of the hemorrhagic diseases are discussed. Rare conditions, such as hereditary pseudohemophilia (von Willebrand) and hereditary hemorrhagic thrombasthenia (Glanzmann) are not clearly defined from a laboratory point of view. The recent work on hypoprothrombinemia and vitamin K and their relation to the hemorrhagic state receives no comment. Methods for studying patients with hemoglobinuria, splenomegaly, liver disease and adenopathies are presented. Emphasis is laid on splenic and hepatic puncture as well as on aspiration of lymph nodes, and the normal and abnormal appearances are well illustrated and discussed. No mention is made of such disorders as plasma cell leukemia, monocytic leukemia, reticulo-endotheliosis, granulocytopenia or the acute hemolytic anemia of Lederer. There is no bibliography, and the few references in the text refer almost exclusively to the work of French authors. A more complete index would enhance the value of the book. The colored plates are good on the whole and are supplemented by numerous black and white illustrations. Because of its epitomized

form this book will prove of little value to the hematologist or internist as a reference work, whereas the general practitioner will find some of the more complete works in the English language more practical for quick reference. The paper binding detracts materially from its usefulness.

Stage Fright and What to Do About It. By Dwight Everett Watkins, A.M., Associate Professor of Public Speaking, University of California, Berkeley, and Harrison M. Karr, Ph.D., Instructor in Public Speaking, University of California, Los Angeles. Cloth. Price, \$1.50. Pp. 110, with illustrations by Zadie Harvey. Boston: Expression Company, Publishers, 1940.

This is a carefree and rollicking little book on stage fright and what to do about it. It is based on sound physiologic principles. Stage fright is defined as a form of fear and especially fear of the unknown or fear of that for which the individual feels himself badly prepared; in other words, lack of self confidence. Stage fright with its quaking knees, trembling hands, cold sweats, internal turmoil, dry throat, unreliable voice and blank mind is likened to the primitive fear which brings about overactivity of the autonomic nervous system and the adrenal medulla. The remedies proposed are simple and sensible procedures which may be summed up in making adequate preparation for public appearances and thus building up a well founded confidence in ability to perform acceptably. Such preparations include suitable attention to appearance, dress, posture, knowledge of subject, preparation of speech and becoming accustomed to public appearances. Nevertheless it is admitted that, in spite of all precautions, some of the greatest stars of stage, screen, radio and the sports world, to say nothing of literary lions, still suffer from stage fright in spite of everything, and in some instances this grows worse as their experience increases. The book contains two conventional physiologic diagrams, a number of photographs of famous actors and on almost every page a "tongue-in-cheek" cartoon indicating the deplorable states of mind and body which characterize the victim of stage fright. This is unquestionably a useful as well as an amusing book and should be helpful not only to those who suffer from stage fright on the occasion of public appearances but also to those who suffer from bashfulness and self consciousness. One of the most virulent forms of stage fright is said to affect the young man in love.

Tomorrow's Children: Proceedings of the First Southern Conference on Tomorrow's Children Held in Atlanta, Georgia, November 9-11, 1939. Harry Blinham, Honorary Chairman. Paper. Price, 75 cents. Pp. 169. New York: Birth Control Federation of America, [n.d.].

This is a record of the Southern Conference on Tomorrow's Children under the sponsorship of the Birth Control Federation of America. It contains the program, the list of sponsors and the remarks of the speakers at the conference, together with a message from Margaret Sanger, honorary chairman of the Birth Control Federation of America. The program included papers on economic, social, population, infant mortality and maternal mortality problems in the South, with particular emphasis on the large proportion of poverty stricken and underprivileged persons, both white and black, in the South and the problem of having to educate one third of the nation's children on one sixth of the nation's available educational budgets, the difficulties involved in the share croppers' problem and the necessity for developing the Negro to take his share of the burden of citizenship. Many of the speakers advocated the abandonment of the poll tax. Almost all the conclusions emphasized the importance of what is popularly called birth control but which the speakers preferred to term "preconceptional care." Instead of the emphasis on legislation which has characterized previous birth control advocacy, it is acknowledged that local obstacles to the spread of contraceptive information are slight indeed. The new emphasis seems to be on the establishment of increasing numbers of clinics. There is much useful factual information in the report and, of course, the points of view of the speakers are of interest, representing as they do so varied a group as a practicing attorney in Tennessee, a publisher of one of Kentucky's principal newspapers, a state president of the League of Women Voters and professors of social science, sociology, public health and economics. The sponsoring committee includes the names of considerable numbers of practicing physicians in the South. The whole purpose of the conference appears to be the promotion of contraceptive practices.

Psychological Studies in Dementia Praecox. By Isabelle Kendig, Ph.D., and Winifred V. Richmond, Ph.D., Psychological Department, St. Elizabeths Hospital, Washington, D. C. Paper. Gratts, plus 50 cents postage. Pp. 211, with 25 illustrations. Ann Arbor, Michigan: Edwards Brothers, Inc., 1940.

This presents a careful and exhaustive study of the intellect in cases of schizophrenia. (The authors continue to use the old terminology and refer to "dementia praecox.") Not only are the intelligence tests carefully presented with separate chapters dealing with general intelligence, patterns of mental functioning in dementia praecox, and the concept of deterioration, but all of the relevant literature referring to this subject has been exhaustively reviewed and quoted when useful. However, the study is of little if any practical value. The authors reach the same conclusion that every progressive psychiatrist who has studied or worked with the schizophrenic has inevitably recognized and that is, to quote from the manuscript, "Despite the great weight of opinion, going back to Kraepelin's own statement that mental efficiency is always diminished to a considerable extent in dementia praecox, we have not found evidence of intellectual deterioration in our patients. . . . While, as pointed out in the case analyses, a sharp decline in the functional level of intelligence may have coincided with the onset of the psychosis, this is usually only conjectural since we rarely know the exact pre-psychotic level. Certainly, as the reexaminations indicate, there is no progressive decay of function during hospitalization, but in most of our patients a gradual recovery in the intellectual sphere corresponding with the disappearance of psychotic symptoms. It therefore seems reasonable to suppose that with complete recovery the original mental level would be regained." This quotation demonstrates what value the monograph may have for future research in schizophrenia.

Convalescent Care. Proceedings of the Conference Held Under the Auspices of the Committee on Public Health Relations of the New York Academy of Medicine, November 9 and 10, 1939. Boards. Pp. 261. New York, 1940.

In recognition of the basic deficiencies which exist in this country in the provision of adequate convalescent care, a conference was held in November 1939 at the New York Academy of Medicine under the auspices of the Committee on Public Health Relations of that academy and with the financial support of the Josiah Macy Jr. Foundation. In order to make the discussions more widely available, they are now published in book form. The first session was devoted to the basic questions of convalescent care and embodied discussions on the physiology and psychology of convalescence by O. H. Perry Pepper, the results of recent research in nutrition with particular reference to the convalescent state by H. D. Kruse, and convalescence and chronic illness by Ernst P. Boas. The subsequent sessions were devoted to convalescent care for various types of patients, psychosomatic aspects of convalescent care, the social, financial and administrative aspects of convalescent care and a summarization of the round table discussions. The actual application of many of the suggestions made should be initiated as soon as possible, since there can be no question that adequate facilities for the care of convalescents represents one of the gravest deficiencies in the medical scene today.

Dependable Modern Treatments for Burns. By Harold Joe Davis. Paper. Price, 50 cents. Pp. 9. Tulsa, Oklahoma: The Author, [n. d.].

This booklet makes an effort to provide a comprehensive but brief and understandable manual for the treatment of burns. The author is a safety engineer who has been impressed by the suffering and difficulty which confront the burned patient. He realizes also that too often there is confusion and mismanagement in the treatment. He briefly discusses ten different methods for the local treatment of burns and wisely states "The important fact to realize in the treatment of burns is that each case must be treated individually. No one treatment is always adequate for all cases or even all areas of the same burn." The author also makes several pertinent and practical statements concerning first aid procedures. However, the booklet seems to undertake the difficult task of supplying technical information to physicians as well as to laymen. The result in general is that the uninformed reader is likely to get a false sense of knowing a great deal about burns. The well informed reader, however, will be disconcerted by the misplaced emphasis and the

frequent failure to mention fundamental general principles. A good example of this weakness occurs in the paragraph on the severity and degree of burns. The author makes the ambiguous general statement "The degree of the burn is not as serious as the amount of surface skin destroyed." Obviously this is a half truth, so briefly stated as to be misleading. True the danger to life depends chiefly on the percentage of body surface burned. The author, however, neglects to mention the important fact that first degree burns heal without a scar, whereas third degree burns always produce scarring and sometimes deformity or disfigurement, even with the best of treatment. This is only one example of the numerous omissions and fundamental errors which mar the value of this otherwise meritorious booklet.

Chronic Diseases of the Abdomen: A Diagnostic System. By C. Jennings Marshall, M.S., M.D., F.R.C.S., Surgeon, Charing Cross Hospital and Victoria Hospital for Children, London. Cloth. Price, \$6. Pp. 247, with 128 illustrations. Boston: Little, Brown & Company, 1939.

Essentially a textbook on differential diagnosis of chronic conditions of the abdomen, this book deals in categorical fashion with abdominal symptoms and signs, listing and discussing each possible etiologic factor. The physical examination and the radiologic and laboratory procedures are fully discussed and should present some helpful aids to the student and practitioner attempting to solve the different problems of the chronic abdominal complaint. A large section is devoted to the analysis of abdominal pain. Those who face with trepidation the difficult differential diagnosis of right lower quadrant pain will find a clear discussion here. The author is emphatic in "laying the ghost" of chronic appendicitis. Epigastric pain is discussed as dyspeptic, nondyspeptic, organic and nonorganic gastric and extragastric. Hematemesis, ascites and jaundice together with such common problems as backache and constipation are amply discussed, particularly with a view toward dispelling some of the old and common mistakes in diagnosis. The discussion of urologic disorders in relation to intestinal complaints is particularly good. The author is rather facetious at times with regard to such problems as adhesions, lumbago and colitis. The book is well written and illustrated with many charts and x-ray plates.

Zwangslose Abhandlungen auf dem Gebiete der Frauenheilkunde. Herausgegeben von Professor Dr. Robert Schröder. Band II: Der Auerlin- (Vitamin B₁) Haushalt in der Schwangerschaft und im Wochenbett. Von Dr. Gerhard Gaehgents. Paper. Price, 5.40 marks. Pp. 76, with 7 illustrations. Leipzig: Georg Thieme, 1939.

This brief monograph is a preliminary report of a study of the metabolism of vitamin B₁ during pregnancy and the puerperium. About two thirds of the report is devoted to a discussion of methods. With the method of Ritsert, which was adopted, there was observed a loss of vitamin B₁ up to 25 per cent in blood, and this must be allowed for in calculating results. The amount of vitamin B₁ in the serum is from 3 to 4 micrograms per hundred centimeters of blood. The vitamin B₁ content in the serum is slightly higher in pregnant women than in normal persons. The normal urinary excretion of vitamin B₁ amounts to from 100 to 200 micrograms daily. The author believes that if the excretion in the urine is below 100 micrograms it indicates a deficiency of vitamin B₁. Pregnant women eliminate about 170 micrograms in each twenty-four hour urine specimen. After parenteral injection, 30 per cent of the dose is excreted in the urine by pregnant women. In healthy puerperal women the vitamin B₁ content of the urine before and after delivery was slightly lower than normal. The relation of the age at which pregnancy occurred was not important with regard to this B₁ content. No information is known regarding the metabolism of vitamin B₁ during the toxemias of pregnancy.

Science Front 1939. By F. Sherwood Taylor, Ph.D., M.A., B.Sc. Cloth. Price, \$2.50. Pp. 301, with 52 illustrations. New York: Macmillan Company, [n. d.].

This book for lay readers gives a quick survey of scientific achievement in 1939. It is written in spritely and popular style but contains considerable organic chemistry and many structural formulas. Included are chapters on science and plant growth, with particular reference to the growth substances and rooting substances; progress in chemotherapy with special reference to the sulfanilamide group of drugs; a chapter on sex and steroids, which contains some statements and suggestions perhaps unsuitable for promulgation to lay readers at this time; a discussion

of research in identifying the nature of living protein substances, including viruses; "the war against cancer"; insulin shock and metrazol treatment of schizophrenia, and a number of chapters of greater industrial and lesser medical interest, such as making oil from coal, progress in television, atom smashing, the quartz clocks, the polar aurora, "our view of the universe" and "the crazy liquid" helium II.

Vital Statistics of the United States 1937. Part I: Natality and Mortality Data for the United States Tabulated by Place of Occurrence with Supplemental Tables for Hawaii, Puerto Rico and the Virgin Islands. Part II: Natality and Mortality Data for the United States Tabulated by Place of Residence. Prepared under the supervision of Dr. Halbert L. Dunn, Chief Statistician for Vital Statistics. U. S. Department of Commerce, Bureau of the Census. Cloth. Price, \$2; \$1.25. Pp. 616; 186. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

These compilations on vital statistics in the United States for 1937 contain an enormous amount of information. From them it is possible to obtain almost any desired information on deaths in the United States: their causes, racial distribution, geographic distribution and the like. Births are also analyzed in a similar manner. Comparisons with previous years make it possible to follow the trends with considerable accuracy. These annual summaries become increasingly mines of information on vital statistics in this country.

Chemistry and Medicine: Papers Presented at the Fiftieth Anniversary of the Founding of the Medical School of the University of Minnesota. Edited by Maurice B. Visscher, Professor of Physiology at the University of Minnesota, Minneapolis. Cloth. Price, \$4.50. Pp. 296, with illustrations. Minneapolis: University of Minnesota Press, 1940.

This volume is made up of a series of fourteen lectures presented by as many specialists covering individual fields of interest. The task of the editor cannot therefore have been irksome, for each of the authors has presented a complete thesis, individual in style, simple enough to be comprehensible by the nonspecialist but comprehensive and intensive enough to satisfy the specialist. This diversity of presentation makes the book entertaining and intriguing. The first section, comprising three lectures, has to do with physical chemistry in medicine and covers colloid chemistry, osmosis and renal function. The second section includes three papers on vitamins, fat in nutrition, and blood clotting. The third section covers four special aspects of immunity and chemotherapy. The last part contains four papers on the chemistry of nerve function. It would be impossible to discuss in any detail the contents of these lectures. Taken collectively they illustrate both the progress and the limitations of chemistry in medicine as well as the mutual interdependence of the two fields. When the physical sciences fail to advance, the biologic sciences stagnate. The biologic sciences, on the other hand, have often, by their demands on the physical sciences, opened up entire new fields in the latter.

Occupational Hazards and the Painter with Special Reference to New York. By Adolph B. Gersh. Paper. Pp. 99, with 19 illustrations. New York: New York District Council No. 9, B. of P. D. & P. of A., 1937.

Painters have frequently expressed concern over the unhealthy aspects of the trade. Not only are they subjected to high accident frequency and severity rates, associated mainly with scaffold and ladder work, but they are regularly exposed to such toxic agents as lead, benzene and its derivatives and homologues, turpentine, alcohol, arsenic and many other pigments, thinners, dryers and similar agents by which the chemist has altered the painting trade. Added to this is the acceleration which modern building methods impose on the painter and decorator as well as other trades with associated fatigue and joint and muscle changes which are attributed to monotonous and repetitious motion. The development of spray painting as a means of maintaining the pace has only intensified exposures to volatile and metallic poisons. This report is intended primarily for consumption by painters themselves, and certain relationships between occupation and morbidity may appear rather fanciful to medical readers. On the whole, however, the preparation of a brochure of this kind, attempting as it does to acquaint workers with the hazards of their trade, appears to be a useful piece of health education which other tradesmen should emulate. The latter half of the book is given over to a discussion of workmen's compensation administration in New York State.

Cura operatoria delle fratture del collo del femore. Di V. Putti. Cloth. Price, 60 lire. Pp. 174, with 227 illustrations. Bologna: L. Cappelli, 1940.

With his usual mastery of presentation the author discusses in the first part the treatment of fresh fractures from the anatomic, physiologic and mechanical points of view. It centers around the use of the author's lag screw, which has the advantage of holding the well adapted fragments closely impacted against one another during the entire process of healing. Abundant x-ray and histologic slides show that the formation of callus proceeds without interference at the impacted surfaces. A large part is taken up with the technic, presented in minutest detail, reduction by traction preoperative preparations. Especially interesting is an x-ray check-up facilitated by a two tube portable machine and by a developer stationed in the operating room, with special rapid developing fluid. This allows the x-ray image to be seen in ten minutes. As a guide he uses the Vals-Lagomarsino instrument, essentially a parallelogram with one side open and one side ending in a point to be inserted through the skin into the head of the femur. The nail is made to pass through the fourth or open side along and parallel to the external part of the instrument, which is graduated. Auxiliary instruments for insertion of the screw such as perforators are used, as well as an external grill to locate the exact side of the femoral head according to the x-ray appearance. Numerous roentgenograms showing excellent results are added. The second part of the monograph deals more shortly with the old and ununited fracture, for which the Kirmisson-Lorenz osteotomy is used. Indication and technic are discussed. The book is superbly published. The illustrations are excellent. It is a fine piece of art as well as a handsome contribution to science.

Les sources de rayons ultra-violet: Leur utilisation en pratiques journalières. Par Jean Saldman, fondateur de l'Institut d'actinologie. Précis d'actinologie, I. Paper. Price, 75 francs. Pp. 292, with 120 illustrations. Paris: G. Doin & Cie, 1939.

This volume, as its title indicates, is concerned chiefly with the physics of ultraviolet rays and the biologic effects produced by them. It will be of interest and value to those who are not already acquainted with the fundamental equipment and procedures used in ultraviolet therapy. Nearly a hundred pages is devoted to details concerning various types of arcs and mercury vapor lamps. The important subject of applicators for local treatments is rather briefly considered. Physical methods of measurement of intensity by radiometric devices and photoelectric tubes, as well as methods and equipment useful for the determination and measurement of biologic effects (including the author's developments along these lines) are covered adequately. The chapters on the choice of lamps, technic of irradiation and therapeutic applications of ultraviolet rays will be of particular interest to radiologists and other specialists who make use of actinotherapy. The volume can be recommended to any who desire a treatise in French on the fundamental principles of the production, measurement and use of ultraviolet rays.

Carbohydrate Metabolism. Four Papers Presented in a Symposium Held at the Meeting of the American Physiological Society at Toronto, Canada, April 29, 1939. Chairman: Professor C. H. Best. Reprinted from *Endocrinology*, Volume XXVI, No. 2, February 1940. Paper. Price, \$1. Pp. 285-351, with illustrations. Menasha, Wisconsin: George Banta Publishing Company, 1940.

This pamphlet consists of considerably amplified versions of the lectures composing the symposium on carbohydrate metabolism. A valuable addition is the extensive bibliography included in each lecture, comprising 257 references in all. This publication is therefore the most recent, authoritative summary and reference work to a subject in which the developments have been bewilderingly rapid and almost revolutionary. The divisions of the subject and the authors are as follows: Glycogen Breakdown and Synthesis in Animal Tissues, by Carl F. Cori; The Liver and Carbohydrate Metabolism, by Samuel Soskin; Adrenal Cortex and Carbohydrate Metabolism, by C. N. H. Long, B. Katzin and Edith G. Fry; The Pituitary Gland and Carbohydrate Metabolism, by F. G. Young. The fact that they are written from the point of view of physiologic research may occasion some little difficulty in the reading of certain sections for those not intimate with the field. However, there is sufficient simplification to make this publication a useful

addition to the library of every practitioner of internal medicine as well as of the research worker. Indeed, for the former it constitutes one of the few available sources of important information which cannot be expected to appear in textbooks for some time to come.

Tuberculosis and Social Conditions in England with Special Reference to Young Adults. (A Statistical Study.) By P. D'Arcy Hart, M.D., F.R.C.P., Member of the Scientific Staff, Medical Research Council, and G. Payling Wright, D.M., M.R.C.P., Sir William Dunn Professor of Pathology, Guy's Hospital Medical School, University of London, London. Foreword by The Marquess of Titchfield, Chairman of Council of the National Association. Preface by Sir Arthur S. MacNalty, K.C.B., M.D., F.R.C.P., Chief Medical Officer of the Ministry of Health. Paper. Price, 3s. Pp. 165, with 7 illustrations. London: National Association for the Prevention of Tuberculosis, 1939.

This is a statistical study of young adults to determine the causes for the lack of decline in the incidence of tuberculosis. The marked decline in the general death rate for tuberculosis is not followed in the incidence and rates of respiratory tuberculosis among the young adult group. This report examines such social conditions as poverty, standard of living, housing, migration and occupation. The study should prove of interest to the tuberculosis specialist as well as to groups of volunteer workers concerned principally with the social aspects of this disease.

Illustrations of Bandaging and First-Aid. Compiled by Lois Oakes, S.R.N., D.N. Cloth. Price, \$2. Pp. 248, with 290 illustrations. Baltimore: William Wood & Company, 1940.

This little volume teaches the art of bandaging and first aid in fractures and hemorrhages by means of 290 pictures and accomplishes its purpose more than adequately. The work is divided into four sections: triangular bandaging, roller bandaging, first aid in hemorrhage and first aid in fractures. Each step in the application of the various bandages or splints for the different possible injuries discussed is illustrated by an excellently reproduced photograph and clarified by a concise legend. A perusal of this small volume will enable the student not only to learn bandaging but actually to master the art quickly with but little effort. The work may be highly recommended to students, nurses and instructors in first aid for use in their classes.

Teaching Wholesome Living in the Elementary School. By Alma A. Dobbs, M.A., Curriculum Division, Los Angeles City Schools, Los Angeles, California. Cloth. Price, \$2.50. Pp. 304, with illustrations. New York: A. S. Barnes & Company, 1939.

This is an excellent text and reference book intended for principals but most particularly for teachers who are concerned with the teaching of health. The book deals with the problem of making wholesome living not a single subject but "an emphasis in education upon a way of living." The author has shown that concern for health came into the school as an adjunct to the business of learning. With scientific advancement came changes in ventilation and lighting. These were found to increase school efficiency. Further observation showed that it was not a part of the child that was involved but that the whole child was to be considered and that physical growth and development must also be considered by the school and not the home alone. Part one of the book deals with the principles of growth and their application to child care. Part two deals with the curriculum and shows where protection and instruction are needed to insure wholesome living. Part three deals with the curriculum and the specific phases of pupil life activities. A rather short glossary is given and a good bibliography that will aid the teacher in developing the program.

Household Hygiene. By J. C. Gelger, M.D., Director, Department of Public Health, San Francisco, California. Paper. Pp. 96, with illustrations. San Francisco, 1940.

This booklet, prepared by the San Francisco Department of Public Health, deals with the extermination of rodents, insects, vermin and noxious weeds. The second part deals with the care of foodstuffs in the home. The third part occupies only a little over two pages and is entitled "Home Care of the Ill" but is really only a summary of the precautions against the spread of contagion. The fourth part deals with the sterilization of dishes. By reason of its brevity, accuracy, completeness and convenient size this should be a convenient pamphlet for the housewife.

Modern Diabetic Care including Instructions in the Diet and the Use of the Old and New Insulins. By Herbert Pollack, A.B., Ph.D., M.D., Instructor in Clinical Medicine, Cornell Medical College, New York. Cloth. Price, \$2. Pp. 216. New York: Harcourt, Brace & Company, 1940.

The purpose of this manual, according to the author, is to make available a nontechnical discussion of diabetes mellitus for the diabetic patient, the physician, the dietitian and other persons interested in the disease. Nevertheless the manual contains much technical physiologic explanation of various phases of diabetes, a discussion which is unnecessary and tends to become difficult for a person with diabetes to follow. Thus there are chapters on the origin of body heat, the body and its food and insulin and food requirement. The author also goes into great detail on how patients should judge their insulin dose based on the urine test. This is a dangerous procedure to recommend to elderly diabetic patients with marked cardiovascular changes if not under the immediate supervision of a physician. There is much advice about which the physician may disagree with the author. The chapter on diets, however, is of practical value and has many fine suggestions.

Food Values in Terms of Household Measures. Prepared by Diet Therapy Section, Cincinnati Dietetic Association. Paper. Price, 10 cents. Pp. 8. Cincinnati: Council on Diabetes, Public Health Federation, 1940.

In eight pages, one of which is devoted to an index, this pamphlet gives the food values of common foods and beverages in terms of common household measures, such as cups, teaspoons, slices of bread or meat, crackers, pats of butter and ordinary size individual fruits. Such caloric tables are necessarily approximate but are nevertheless useful to the individual who cannot or will not weigh his food. The pamphlet includes no recommendations for any kind of diet. Its compact form and convenient size should make it useful to any one interested in dietary regulation or compelled to cook for or serve such a person.

Clinical Parasitology. By Charles Franklin Craig, M.D., M.A., F.A.C.S., and Ernest Carroll Faust, M.A., Ph.D., Professor of Parasitology in the Department of Tropical Medicine, Tulane University of Louisiana, New Orleans, Louisiana. Second edition. Cloth. Price, \$8.50. Pp. 772, with 244 illustrations. Philadelphia: Lea & Febiger, 1940.

The thorough revision of this authoritative textbook on parasitology must be welcomed wholeheartedly by teachers as well as by those whose professional activities require close familiarity with animal parasites and the diseases caused by them. The writing is admirably terse but covers the introductory aspects of the subject well and can be easily supplemented by consulting the important references to the literature cited at the end of the book. Both the subject and the author indexes are satisfactory.

Silicosis: Proceedings of the International Conference Held in Geneva from 29 August to 9 September 1938. International Labour Office Studies and Reports Series F (Industrial Hygiene) No. 17. Paper. Price, \$1.25; 6s. Pp. 223, with illustrations. Washington, D. C.: International Labour Office; London: P. S. King & Son, Ltd., 1940.

The discussions at the second International Conference on Silicosis failed to develop information not well known to advanced students in this field. Evidently controversial matters were purposely omitted from the agenda and from the printed conclusions. Nevertheless these papers and special reports are reliable estimates of the present status of our knowledge about causation, diagnosis and prevention of silicosis at least regarding the points on which the experts are inclined to agree. Some interesting details of new laboratory procedures are presented. These conferences are intended to bring representatives of nations just entering this field of activity down to date and to refer them to the experiences of others who have been in contact with these problems over a long period.

Diet Manual of University Hospital, University of Michigan. Revised edition. Paper. Price, \$1.25. Pp. 98. Ann Arbor, Michigan: George Wahr, Publisher, 1940.

This constitutes a collection of the diets used at the University Hospital at the University of Michigan, Ann Arbor. Reference to the desired diet list is made easy by the index. For those institutions which do not have satisfactory diet lists of their own, this would be helpful and could easily be supplemented or amended.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

10:361-424 (June) 1940

- Relations Between Specific Immunity, Allergy and Anaphylaxis in Tuberculosis. H. J. Corper, M. L. Cohn and A. P. Damerow, Denver.—p. 361.
- Carbohydrate Fermentation Reactions of Staphylococci. G. H. Chapman and M. H. Stiles, New York.—p. 380.
- Monocytic Leukemia of Naegeli and Schilling Types. C. H. Watkins and B. E. Hall, Rochester, Minn.—p. 387.
- Plasma Prothrombin Determination. D. H. Kaump and J. H. Greenwood, Temple, Texas.—p. 397.
- Primary Lymphosarcoma of Small Intestine: Report of Case. E. L. Benjamin and F. Christopher, Evanston, Ill.—p. 408.
- Tubercle Bacillemia in Old People. A. Arnstein, London, England.—p. 414.

1-18 Section B 1-26 Section C 1-32 Section D

Section A

- Family Studies in Eastern Health District: II. Accuracy of Statements of Age on Census Records. P. M. Densen, Baltimore.—p. 1.
- *Cancer in Its Relations to Climatic Conditions Acting During Childhood and Adolescence. S. Peller, C. S. Stephenson and C. G. Souder, Baltimore.—p. 39.

Section B

- Tissue Response of Normal Rabbit to Certain Lipoid Components of Typhoid Bacillus. E. W. Dennis, Beirut, Lebanon, Syria.—p. 1.

Section C

- Insectary Rearing of Anopheles Quadrimaculatus: Preliminary Report. R. L. Crowell, Wilson Dam, Ala.—p. 12.
- Effect of Environmental Temperature on Experimental Trypanosomiasis (Trypanosoma Cruzi) of Rats. M. H. Kolodny, New York.—p. 21.
- Development of Acquired Immunity in Avian Malaria: Note. R. Hegner, Baltimore.—p. 24.

Section D

- Incidence of Trichinosis in 300 Autopsies at the University Hospital, Ann Arbor, Mich. L. Catron, Ann Arbor, Mich.—p. 12.
- Experimental Studies on Validity of Species in Genus Strongyloides. D. L. Augustine, Boston.—p. 24.

Cancer and Climatic Conditions.—Peller and his co-workers point out that in the United States Army and Navy the incidence of cutaneous and lip cancer has been found to be several times higher and that of internal cancer substantially lower, than for a comparable group in the civil population of such cities as New York, Chicago, London or Vienna. For these cities one could hardly estimate a cutaneous and lip cancer ratio higher than 12 to 15 per cent of all cancer cases in the age groups below 64. In the Army, white active personnel, 34.6 ± 2 per cent and in the Navy 42 ± 3.3 per cent of all cancers originate on the surface of the body. The ratio of cutaneous and lip cancer in young persons in the Navy declined inversely to the age. The younger personnel is more exposed to outdoor life, the sun's rays, wind and other irritant factors than in later life. In the Army, white cancer patients born south of 40 degrees latitude, 45.4 ± 3.2 per cent suffered from epithelioma of the skin or lip, while the corresponding datum for cancer patients born north of this latitude was 26.1 ± 2.5 per cent. In the age group from 20 to 34 the ratio for the Southern born was 51.6 ± 5.2 per cent and for the Northern born 16.7 ± 4.4 per cent. The location of garrison was entirely unrelated to the latitude of birth or to the state of birth. The differences therefore must be determined by preservice conditions. In the group born in the South, 49.9 per cent of all its cancers originated in the skin or lip; while in the group born north of 40 degrees latitude the surface of the body accounted for only

27.4 per cent of its malignant growths. The authors conclude that the high frequency of cancer of the skin and lip and consequently the low frequency of internal cancer and the low total cancer mortality of the age groups 20 to 64 in the Army and Navy depend essentially on the exposure to dermatotropic climatic conditions in childhood, adolescence and manhood. Exposure to actinic conditions during adolescence and youth seems more important in its effect on the frequency of surface cancer and the total cancer mortality than is exposure during manhood. A systematic exposure to ultraviolet rays during childhood and adolescence may become an effective measure of preventive medicine in combating cancer as a cause of death.

Desensitization to Wheat with Acetylcholine Derivative.—Pearson reproduced the focal reactions such as bronchial asthma, vasomotor rhinitis, eczema, urticaria and angioneurotic edema of seven patients allergic to the ingestion of wheat with acetyl-beta-methylcholine chloride (mecholy), an acetylcholine derivative. The substance was administered daily for from twenty to sixty days in increasing doses, according to the tolerance of the individual, during a controlled symptom-free period. When wheat was again added to the patients' diet the original symptoms did not recur. The patients have remained well or greatly improved for one year or longer. Previous attempts to desensitize four of the patients with wheat extract had been unsuccessful, and two previous injections of histamine did not influence the course of the illness. This method of therapy is particularly significant because it is in accord with the new knowledge of the chemical transmission of nerve impulse, a concept which will influence future study of many functional disorders. The effects of injecting this acetylcholine derivative are probably superficial and although the status quo is altered there is little change in the basic hypersensitive or cholinergic states. Fundamental alterations in the method of living, working, eating and thinking may be necessary to enable the autonomic nervous system to readjust itself. Patients whose allergic reactions tend to asthma, eczema, vasomotor rhinitis, urticaria and angioneurotic edema often present other features of cholinergia such as excessive sweating, salivation, indigestion of hyperacidity type, intestinal spasticity and dermatographism.

Hemolytic Reactions Following Transfusions of Homologous Blood.—Wiener and Peters cite three instances of hemolytic transfusion reactions belonging to "intragroup" incompatibility. Intragroup hemolytic reactions have been greatest in patients receiving repeated blood transfusions and in postpartum cases. The warning not to use the same donor for patients receiving repeated transfusions is not sufficient to exclude transfusion reactions, as the antigens responsible may occur in a considerable percentage of individuals. The authors believe that for their first two patients repeated transfusions from a single Rh (an agglutinable property of human blood recognized by immune serums for rhesus blood) donor would

have been safer. The appearance of the iso-agglutinin designated as anti-Rh in the serum of these two patients is explained as the immune response to the injection of Rh+ blood into Rh- individuals, the blood group playing no part. Following the appearance of the anti-Rh agglutinins the transfusion of Rh+ blood gave rise to hemolytic reactions. The reactions of the anti-Rh serums corresponded with those of immune rabbit serums prepared by Landsteiner and Wiener by the injection of rhesus blood. The frequency distribution of agglutinin Rh in the general population is approximately 85 per cent Rh+ and 15 per cent Rh-. Postpartum patients who have hemolytic reactions following transfusions of the proper group, though never transfused previously, should belong to the same category as the patients immunized by repeated transfusions. Some writers consider leukemia and hemolytic icterus contraindications to blood transfusion, as hemolytic reactions have been observed to follow transfusions of apparently compatible blood. The formation of immune iso-antibodies seems the most plausible explanation, because such patients are usually given many blood transfusions. No single in vitro prophylactic technic will cover every exigency of intragroup hemolytic reactions. The authors advise the following cross-matching technic in addition to the usual grouping and cross-matching tests, as it will anticipate most reactions of this sort: 1. Two drops of the patient's serum, preferably separated from the clot at refrigerator temperature, are mixed with one drop of donor's cell suspension in a small test tube. 2. In a second tube a similar mixture of the patient's serum and the patient's cells is set up. The tubes are placed in ice water for five minutes, then centrifuged while still cold and the mixtures are gently shaken. If neither tube shows a macroscopic or a microscopic reaction the donor is compatible. If both tubes show a reaction an auto-agglutinin is being dealt with and the donor probably can be used without danger. If tube 1 shows agglutination and tube 2 does not, the donor is incompatible. In any event, if time permits the serologic test should be supplemented by a biologic test. In citrate transfusions the first 50 or 100 cc. of blood can be injected very slowly and if a chill results (within the hour) the infusion should be stopped and another donor tried. This procedure would probably prevent any serious consequences, as 100 cc. of incompatible blood is hardly enough to cause a fatal reaction. In a series of fifteen hemolytic reactions with ten fatalities analyzed by Bordley, the patients receiving less than 350 cc. of blood recovered.

Superior Pulmonary Sulcus Tumors.—Morris and Harken report eight apical chest tumors, three of which answer the criteria of a superior pulmonary sulcus tumor as a specific entity. The series exhibits the classic picture of Horner's syn-

drome associated with an apical shadow, characteristic pain distribution and muscular atrophy. In three cases the apical tumor was shown to be either bronchogenic or metastatic carcinoma and serves to illustrate the nonspecific nature of the syndrome itself, two cases which were undoubtedly true Pancoast tumors were disqualified because of incomplete pathologic studies and the remaining three instances fulfill the criteria of the entity described as primary "pulmonary sulcus tumor." The authors postulate the following criteria: (1) clinical evidence of an apical tumor expressed in terms of pressure-destruction effects on adjacent nerve and osseous tissues (Hare's syndrome), (2) histologic evidence of epithelioma and (3) pathologic evidence (based on biopsy, operative and postmortem studies) which proves the extrapulmonary character of the tumor, its "lack of origin from lung, pleura, ribs or mediastinum" and its primary nature excluding all possible sources of metastatic origin. If this standard is applied, only four instances in literature conform to it. With the authors' three there is a total of seven authentic cases. Diagnosis of Pancoast tumor is conditioned on the foregoing criteria. The "Pancoast syndrome" is decidedly not a specific manifestation of the "superior pulmonary sulcus tumor" but may be initiated by various types of neoplasms as well as other pathologic conditions occurring in proximity to the pulmonary apex. The syndrome attributed to Horner was fully described by Hare thirty-one years previously and should be known as Hare's syndrome. In its early stages the condition is almost invariably treated as arthritis, neuritis, apical tuberculosis, angina pectoris or subdeltoid bursitis. Early x-ray study in obscure conditions of this type may well bring this condition within the realm of efficient surgical therapy. Roentgen therapy has proved futile as a method of treatment. Superior pulmonary sulcus tumor is characterized by (1) involvement of the cervical sympathetic chain, (2) pain referred to the shoulder, arm and hand, associated with muscular atrophy—indicative of invasion of the brachial plexus and (3) an apical tumor with destructive infiltration of contiguous ribs and vertebrae.

Leukoplakic Vulvitis.—According to Sparrow, much of the confusion surrounding leukoplakic vulvitis is due to the fact that its etiology is not known. There is considerable evidence that an ovarian dysfunction or cessation of ovarian hormone activity is an important etiologic factor. The conclusion to be drawn from the work of various observers is that normally ovarian hormone exerts some protective influence over the genital skin and that in certain women the withdrawal of the hormone results in an inflammatory process with leukoplakia and kraurosis as its principal gross manifestation and pruritus its chief symptom. Such a rationalization of the etiologic process may be logical, but it is open to criticism. There must be other factors, as yet unknown, that are important causative agents. The symptom that sends most of these patients to a physician is severe and intractable pruritus, with associated excoriations and fissures secondarily infected with burning, stinging, soreness and dyspareunia. Leukoplakic vulvitis is difficult to differentiate from other conditions associated with pruritus. The disease is of major importance because it is definitely a precancerous condition. In ninety-six cases of leukoplakic vulvitis reported by several authors 50 per cent were malignant. All forms of therapy have been applied in the treatment of leukoplakic vulvitis, but surgical intervention is perhaps the method of choice. The entire involved area must be resected. This may require the removal of the clitoris, perianal skin, the labia minora and most of the labia majora. This procedure successfully relieves the distressing symptoms and it eradicates the precancerous condition. The author cites six cases in which vulvectomy was performed. The average age of the patients was 52 years. Pruritus, pain and soreness from excoriations were their chief complaints. The first patient was operated on seven years ago, the most recent one year ago. The process continued to spread in two instances. This necessitated a second operation. An intra-epithelial epithelioma was found in one case. One patient had complete relief for almost two years, when a reddish discoloration of the skin about the vagina and

rectum appeared and an intermittent pruritus returned. A culture showed an abundant yeast growth and it has been very difficult to control the pruritus. In the only Negro woman of the series two years after operation there was complete loss of pigment of the skin about the rectum. There were no subjective symptoms. A biopsy of this area showed hyperkeratosis and absent rete pegs and fibrosis, collagenous changes and lymphocytic infiltration in the corium. The basal pigment layer stopped abruptly at the border of the lesion. The pruritus returned one year after operation in another case. There were no fissures or leukoplakic plaques. Cultures were negative for yeast or fungi. A biopsy showed, chiefly, hyalinization of the corium, atrophy of the rete and some dyskeratosis. There were no complications in the remaining case. The complications in four of the cases were treated by applications of an ointment, suggested by Foss, containing 1,800 rat units per gram of estrogen and 15 mg. of crystals. The pruritus of two patients was temporarily relieved. The ulcers in one patient disappeared in part, but in areas of tension they continued to appear at intervals.

Plasma Transfusion in Burns.—Elkinton and his associates studied five cases of moderately severe burns in the light of recent experimental and clinical observations. Their data are in accord with the view that the fluid imbalance is primarily due to an altered capillary permeability with a shift of fluid and protein into the tissues, rather than an external loss. The restoration of plasma protein by means of plasma transfusion is a rational treatment for this fluid shift. They found that the loss of plasma protein continues until the thirty-first to the fortieth hour. During this period excessive hemoconcentration may be prevented by small repeated transfusions of plasma. After the fortieth hour, when the capillaries have regained their impermeability to protein, the deficit of plasma protein may be corrected by a large plasma transfusion. The amount of protein required is calculated by a formula based on hematocrit values, plasma protein concentration and body weight. This regimen permits the restoration of plasma volume to normal without the administration of excessive amounts of protein-free fluids.

Determinations of Serum Lipase.—Johnson and Bockus determined the serum lipase in 371 cases. The determinations were performed by one or the other of two persons. All values in excess of 1 cc. of a twentieth normal solution of sodium hydroxide were considered abnormal. Readings above this level were obtained from fifty cases or eighty-six separate determinations. The study confirms the reports of others that pancreatic disease shows the highest incidence of increased values for serum lipase. In nine of eleven cases of acute pancreatitis and in five of eight cases of proved cancer of the pancreas, pathologic values for lipase were obtained. Furthermore a positive test was obtained in only one of thirty-one cases of cholelithiasis without jaundice and without a previous history of jaundice, whereas in 31 per cent or nine of twenty-nine cases of cholelithiasis with jaundice or with a history of jaundice values above 1 cc. were obtained. The study does not support the view that hepatocellular injury causes an elevation of the serum lipase. Normal values were obtained in fifteen cases of so-called catarrhal jaundice, two cases of toxic or infectious hepatitis and twelve cases of hyperthyroidism. No relation between hyperbilirubinemia and the values for serum lipase was observed when simultaneous determinations of serum lipase and bilirubin were made on the same blood samples from forty-four jaundiced patients. This may give additional evidence against the theory of a hepatic causation for hyperlipasemia. High lipase values were obtained in seven of twenty-four cases of cirrhosis of the liver and in two cases of hepatic tumor. Four patients with intestinal obstruction had elevated values for serum lipase. The authors found no similar reports in the literature. If the observation is confirmed, the serum lipase test will have another important clinical application. They feel that the serum lipase determination is of considerable clinical importance and that it warrants a wider application.

Roentgen Therapy and Survival in Primary Carcinoma of Lung.—Steiner studied the microscopic effects of roentgen therapy on primary cancer of the lung and the effects of roentgen therapy on the survival period of patients with pulmonary carcinoma. The material for the study consisted of twenty-one patients with primary cancer of the lung who received roentgen therapy and as a control sixty-four patients not receiving such treatment. All were studied post mortem. In the twenty-one cases irradiation of the tumor with doses up to 5,000 roentgens did not destroy the carcinoma as judged by microscopic standards. The smallest dose which produced visible damage was 1,490 roentgens, but the carcinocidal dose was probably above 5,000 roentgens. In a metastatic carcinoma of the skull 3,800 roentgens produced marked degenerative changes, apparently destroying the tumor cells, although the microscopic examination

was not extensive enough to justify a final conclusion. Squamous cell carcinomas and adenocarcinomas of the lung were more radiosensitive than were the undifferentiated carcinomas, which, contrary to their microscopic appearance, were either highly radioresistant or highly radiorecuperative. The microscopic changes after irradiation consisted of degenerations, retrogressions or alterations in cell type and in tumor architecture. They resembled those which have been described for other types of carcinoma. Undesired effects of irradiation on tissues and organs near the primary carcinomas were not seen. Survival was not notably prolonged by irradiation. The twenty-one patients survived for an average of 11.9 months after the onset of symptoms as compared to 10.5 months in fifty-three control patients.

Hypoglycemia.—Hart and Lisa found that hypoglycemia (blood sugar below 80 mg.) occurred in 2,371 of 21,000 patients whose blood sugars were taken on a fasting stomach. Of these, 751 fell below 70 mg. A few blood sugar values were as low as 28 mg. without shocks. The authors conclude that low blood sugar readings are apparently not associated with any disease or group of diseases. It is possible that normal individuals may

have occasional low blood sugar values with an otherwise normal blood sugar. Either spontaneous hypoglycemia is not a common condition or routine fasting blood sugars are not reliable guides to its occurrence.

Postoperative Venous Thrombosis and Pulmonary Embolism.—Culp analyzes eighty-eight cases of pulmonary embolism encountered at the Brady Urological Institute during the last twenty years. There were thirty-two cases of fatal embolism proved at necropsy, eleven of presumptive fatal embolism in which necropsy was lacking, twenty-one of pulmonary infarcts from which the patients recovered, four infected pulmonary infarcts recognized at necropsy and twenty cases with incidental pulmonary infarcts discovered at necropsy. The majority of the thirty-two cases of proved fatal pulmonary embolism occurred in private patients more than 60 years of age, after operations performed under spinal anesthesia. Continuous intravenous infusions appeared to be a factor in producing thrombosis in the lower extremities in four instances. Marked variations from normal weight, excessive drop in blood pressure during operation, marked abdominal distention, postoperative instrumentation and organic circulatory disease, in individual cases, probably were contributing factors. In only 18.8 per cent was the thrombosis recognized clinically. Any untimely activity seemed to be capable of dislodging thrombi. Analyses of the eleven cases of presumptive fatal pulmonary

embolism revealed essentially the same contributing and the same nonessential factors as did the foregoing cases. The majority of the twenty-one nonfatal pulmonary infarcts occurred during the past ten years in private patients more than 60 years of age given spinal anesthesia. Continuous intravenous infusion was directly responsible for two cases. Marked drop in blood pressure during operation, postoperative abdominal distention, severe wound infection and circulatory disease were contributing factors in individual cases. Only 23.8 per cent of the patients presented clinical evidence of thrombosis. Some of the small emboli may have originated in the pelvis or operative area. The four patients with fatal infected pulmonary infarcts after perineal prostatectomy performed under caudal anesthesia were undernourished and more than 60 years of age. Severe wound infections were present. Associated circulatory disease, marked drop in blood pressure during operation and persistent abdominal distention may have been factors. All the patients had a clinical course simulating pneumonia. Thrombosis of the leg was diagnosed clinically in only one case and was proved at necropsy in two. The emboli in the other two cases may have come from the operative area in the pelvis. The various causes of death in the twenty cases of small pulmonary infarcts recognized at necropsy and which apparently played no part in the fatalities were pyelonephritis and uremia, pneumonia (lobar and lobular), coronary occlusion, generalized peritonitis, septicemia, heart failure and cerebral hemorrhage. Thrombosis of the lower extremity was observed clinically in five cases and demonstrated in the leg at necropsy in six, and in the pelvic veins in four; in ten the source of the embolus was not demonstrated at necropsy. The following prophylactic measures are recommended: 1. Continuous intravenous infusion should not be used unless absolutely necessary. 2. Every effort should be made to prevent peripheral venous stasis by adequate treatment of associated circulatory disease, fall in blood pressure, postoperative abdominal distention and by the elimination of unnecessary pressure on peripheral vessels due to strapping and the like. 3. Wound infections should be minimized by careful aseptic operative technic and mild bacteriostatic agents. Drainage of postoperative abscesses should be established immediately. 4. The greatest need is the recognition of thrombosis in the lower extremity. The legs should be measured on admission, before operation and before patients get out of bed. 5. Untimely activity should be avoided in the presence of thrombosis. Absolute bed rest is the most conservative and most practical treatment for thrombosis and prevention of embolism.

Cigaret Smoking, Metabolism, Heart and Breathing Rate.—Hiestand and his associates studied the immediate effects of smoking on the metabolic and heart rate of thirty-nine average persons grouped as heavy smokers, light smokers and abstainers. The effects over a longer period of twenty persons were also determined. These persons were all habitual smokers. Each was in a basal condition and none had smoked since the previous day. The greatest increase in metabolic rate occurred in a confirmed woman smoker who inhaled deeply. Her metabolic rate rose 40.7 per cent immediately after smoking. Five individuals showed a decrease in metabolic rate. One individual in the second series (basal persons) showed a decrease, the rate of metabolism falling 8.5 per cent immediately after smoking and continuing to fall fifteen minutes later, after which it returned to nearly normal. An increase in metabolic rate of from 5 to 10 per cent occurred in the greatest number of cases. The average increase was 8.9 per cent. The maximal metabolic

rate of three persons was reached fifteen minutes after smoking, at thirty minutes in three and at forty-five minutes in four. The remaining ten showed the maximal metabolism immediately after smoking. Most of the persons showed a second slight rise at about forty-five minutes. The total percentages showed that there occurred simultaneously an increase in metabolic rate, an increase in heart rate, a decrease in breathing rate and a temporary decrease in oxygen pulse, followed by a rise back to and above the normal level. The average increase in metabolic rate for the eighteen men was 7.7 per cent and for the twenty-one women it was 9.9 per cent. The average increase in heart rate for the men was 5.9 per cent and for the women it was 6.4 per cent. In general there was a tendency for those who inhaled the most smoke to show the greatest physiologic changes. Profound changes also occurred among abstainers and among those who smoked only occasionally. Habitual smokers who inhaled little or no smoke tended to show only moderate effects. Cigaret smoking caused an increase in metabolic rate in 82 per cent of thirty-nine subjects, a decrease occurred in 13 per cent and no immediate effects were observed in 5 per cent. The rate of breathing decreased immediately after smoking and returned to normal in about forty-five minutes.

Fasting Exercise Blood Sugar Curve.—Reveno describes a test for gaging the severity of diabetes. It consists in making three blood sugar estimations at intervals of three hours on the fasting patient while he is ambulatory. The resulting curves fall into three groups: (1) a continuous descent from the initial reading, all levels being not far above the normal values, (2) a continuous descent from the initial reading, with all levels considerably higher than the normal values, and (3) a group of curves, none of which show a continuous descent, with at least one of the last two readings being higher than the initial value. The curves of the persons with mild diabetes that are readily controlled by diet alone or combined with a single dose of protamine zinc insulin fall into the first two groups. In the third group are the persons with severe diabetes. Of fifty persons with diabetes studied, fifteen fell into the first group, nineteen into the second and twelve into the third. Two patients with acromegaly and diabetes showed flat curves and two patients were tested during treatment with insulin. One showed a descending curve typical of mild diabetes, when, in fact, his was a severe diabetes requiring both types of insulin for control. The other, receiving a single daily dose of protamine zinc insulin, showed a flat type of curve resembling the normal. Four similar curves were encountered in the group of patients with mild diabetes on restricted diets for varying periods before testing. This experience indicates that the test is not applicable to patients under treatment, in which case it is only a measure of the adequacy of treatment. The test appears to be most useful for the new or untreated patient with diabetes. By gaging the severity of his disease, a greater degree of efficiency, with economy of time and expense, may be attained in planning therapy.

Sarcoma of Prostate.—Stevens and Barringer report sixteen cases of sarcoma of the prostate and three of anaplastic carcinoma. They suggest an irradiation procedure which they believe may lead to the control of some of these cases and to a greater extension of life in many more. Only a rare case of sarcoma of the prostate is controlled for more than a few years by present methods. Prostatic abscess, prostatic carcinoma, bladder tumor, extravascular tumor, cyst of the prostate and massive stone of the prostate may be mistaken for prostatic sarcoma. Roentgen treatment as a diagnostic test should not be disregarded. Many of these tumors are highly radiosensitive. High voltage roentgen therapy, 300 roentgens daily to four ports until a total dosage per port of perhaps 1,200 roentgens is given, may reveal in three or four weeks a marked recession of the growth. This information is not as reliable as that obtained from aspiration biopsy but is of great value. Clinically there are two distinct groups of these tumors. In one group are patients subjected to prostatectomy under a diagnosis of benign hypertrophy and known to have a malignant tumor only after microscopic examination of the tissue. These cases are usually and fortunately of low malignant grade, generally radio-insensitive, and, while a prostatectomy may not be the operation of choice, it is unavoidable. Such cases are either watched carefully for recurrence or are immediately treated by external and interstitial irradiation. The other group of patients, in whom the presence of a tumor of unusual malignant grade is recog-

nized, presents a different problem. Operation of any sort seems to be consistently fatal, even if followed by radiation therapy. A modified form of irradiation for these patients, similar to that which has been applied to control Wilms tumors of the kidney, is suggested. The theory behind the treatment is that a prolonged external irradiation produces a slow sclerosis of blood vessels which is apparently necessary to control the growth. While the blood supply of the prostate is not as great as that of the kidney, it is copious enough to warrant this type of therapy. In a sarcoma of the prostate the authors would attempt to make an aspiration diagnosis and immediately put the patient on high voltage roentgen therapy even if no microscopic diagnosis was made. They would give the patient 200 roentgens daily at 70 cm. distance to four or five ports and continue this for six or more months. This requires patience and persistence, but in view of the paucity and questionable nature of the reported cures it seems worth a trial. If retention by catheterization is impossible, a semipermanent suprapubic tube should be inserted. The authors conclude that their experience and literature demonstrate the superior value of irradiation over surgical procedures.

Chondroitin for Migraine.—Drewyer used chondroitin in capsules containing 0.6 Gm., four capsules three times a day after meals, as recommended by Crandall, in the treatment of sixteen cases of migraine and fourteen of idiopathic headache.

The patients have been under treatment for from six months to three years and 67 per cent of them have been completely relieved of their symptoms, 13 per cent have been partially relieved and 20 per cent experienced no benefit. Among the failures those with true migraine were often relieved by ergotamine tartrate intramuscularly. The author believes chondroitin to be a valuable adjunct in the prevention of these types of headache.

Tuberculosis Among College Students.—According to Lyght, Myers and his co-workers established a student chest clinic at the University of Minnesota twenty years ago. Today there are nearly 200 institutions of higher education in the United States providing some degree of tuberculosis case finding among their students. A report for 1938-1939 lists 282 replies to a questionnaire from colleges and universities, of which 165 reported some form of tuberculosis program in operation. The institutions ranged from small schools with an enrollment below 500 through large institutions enrolling from 4,000 to 16,000 students. All sections of the country were represented. Of these 143 test with tuberculin, while twenty-two resort to x-ray study as the first step in their procedure. The difficulties which have led to adoption of the latter method include real or fancied student distaste for the tuberculin test, a high incidence of positive reactors, time, energy and expense demanded by careful tuberculin testing. Nonetheless prior tuberculin testing is advocated, since it provides the only sure way of discovering more than 90 per cent of the presently infected individuals. Furthermore, the retesting of negative reactors, preferably annually, gives definite indication of tuberculo-protein allergy shortly after its development or its resumption by those few who may have achieved anergy for a time, only to revert to positivity through reactivation of once inactive, apparently well calcified, lesions. The benefits of tuberculin testing so far outweigh the admitted bother and the negligible expense that the method should be preserved intact, its use spread rather than abandoned for what may be a questionable short cut. Figures for 1937-1938 and for 1938-1939 are almost identical and indicate that tuberculosis can be found early by any one willing to look for it. Last year in the 165 colleges supporting case finding, enrolment totaled 348,713 students. Determined search for tuberculosis disclosed 241 clinically active cases, 368 diagnosed as apparently arrested, or 609 newly found cases. Of these, 151 students withdrew from college because of their lesions. There were an additional 320 old cases not included in the foregoing back in college under supervision. In comparison,

of 129,851 students enrolled in 117 colleges without case finding programs there were four cases diagnosed as clinically active, fifteen as apparently arrested, and ten formerly diagnosed back in school. Only four students left college because of tuberculosis. In the first group of colleges the protected, investigated student population was less than three times the volume of that in the second group, yet its active cases were sixty times as numerous and those advised to leave college for their own good and for the safety of others were thirty-eight times as many. Physicians in general and tuberculosis specialists in particular should cooperate with the student health doctors who are attempting to popularize a campaign built around the words "early" and "preventive." Every far advanced case and every fatality was once a minimal case.

Early Diagnosis of Tuberculosis.—According to Mariette, in Hennepin County the search for the unknown case of tuberculosis is a cooperative program. It is participated in by the Hennepin County Tuberculosis Association, the Glen Lake Sanatorium and the private physician who reports his cases to the sanatorium. This cooperative survey, begun in 1925, includes the school child and his adult contact both in the school and in the home and the contacts of the new cases of tuberculosis reported to the health department. The work has two phases: educational or publicity directed by the Hennepin County Tuberculosis Association and medical directed by the sanatorium but including the private physician. The Tuberculosis Association in its educational work gets in touch with the schools and sells the idea of a school survey to the parents and the school employees. On the effectiveness of this publicity, securing signed cards of consent for the tuberculin cutaneous test, the success of the survey depends as far as it pertains to the number of children, school employees and adult contacts studied. In 1940 about 70,000 people in the United States will die from tuberculosis and about 500,000 will be made ill by it. The task of case finding is tremendous.

Single Trauma as Etiologic Factor in Carcinoma.—Leighton and Schmidtknecht review the histories of cancer cases at the Barnard Free Skin and Cancer Hospital with regard to the incidence of a single trauma as the etiologic cause. Sarcomas and internal and mammary cancers were excluded and only cases of external carcinomas were selected, as this permitted the patient to know whether there was a tumor or any visible defect prior to the injury. Seventy-nine case histories of definitely proved carcinoma with antecedent single injury were found. The statements in these histories should have as much value as any other etiologic factor, as there was no medicolegal or compensation question. The single injuries reported by the patients were blows from wood, hammers or falls, razor cuts (circumcision), burns (from hot metals, cigarettes or acids), laceration, excoriation and crushing injuries. Seventy-three of the patients were between 40 and 80 years of age when the injuries were sustained. Only five patients gave a history of familial carcinoma. Thirty-one of the cancers appeared in from one to ten months after injury, and forty-two others in less than three years. In the majority the original lesion failed to heal. There were seven carcinomas of the penis, and one of these occurred on the shaft, an unheard of site. The authors point to the fact that, while no one believes that trauma in itself is the cause of cancer, the trauma apparently sets off something, and from their experience it is the exciting or instigating cause in certain cases.

Vitamin K Deficiency in Absence of Jaundice.—Mackie points out that the deficiency of prothrombin in the blood of jaundiced individuals and the demonstration of the role of vitamin K in the maintenance of normal prothrombin values promptly led to successful clinical trial with vitamin K in cases of obstructive jaundice. However, prothrombin deficiency has been encountered in other conditions. The author investigated the vitamin K status of 277 miscellaneous medical and surgical cases by determining the prothrombin time of the plasma according to the method of Quick. He observed elevated prothrombin time in fifty-seven cases in which there was neither jaundice nor other evidence of hepatic disease. Six of these, three of them complicated by severe hemorrhage, are presented in detail. There was one case of Banti syndrome, one of tropical sprue complicated by chronic intestinal obstruction, two of ulcerative colitis and two of regional enteritis. Physical examinations and icterus indexes did not demonstrate advanced hepatic disease. Precipitating factors appear to have been defective diet, defective absorption from the intestine and major surgical procedures. Vitamin K is known to be present in many different foodstuffs and is said to be produced in the intestinal tract by bacterial action. It is a fat-soluble substance which requires the presence of bile salts for absorption. The formation of prothrombin necessitates not only vitamin K but a functionally active liver. It is apparent that vitamin K deficiency may arise in several different ways. Exclusion of bile from the intestine by obstructive jaundice or external biliary fistula may prevent absorption. Insufficient secretion of bile acids will act similarly. Disease or altered physiology of the intestine may produce this avitaminosis by impairing the absorptive function even in the presence of adequate sources and a functionally active liver. Defective diet alone may produce this type of deficiency despite the theoretical source of the vitamin from intestinal bacterial action. Vitamin K deficiency may occur in a variety of conditions unaccompanied by jaundice or evidence of serious liver disease. The

cases studied emphasize the clinical importance of this deficiency and illustrate certain of the potential mechanisms that may produce avitaminosis K. Correction of a defective diet alone may suffice to restore an elevated prothrombin time to normal. In certain cases without jaundice, vitamin K alone or dehydrocholic acid alone will suffice; in others bile acids and vitamin K are required. The response of certain cases to the exhibition of dehydrocholic acid alone suggests a qualitative or quantitative defect of bile secretion.

Submarine and Diving Medicine.—Johnson discusses the dangers to which submarine crews and professional deep-sea divers are exposed in the discharge of their duties and the part of medicine and mechanical ingenuity in meeting and neutralizing these dangers. Most of the problems are in the field of physiology, especially of respiration and interchange of gases under pressure in the tissues of the body. Submarine personnel is rigidly selected and exactly trained. Oxygen control embraces the three phases of oxygen supply, carbon dioxide elimination and wet bulb temperature regulation. Oxygen needs in submarine work, anoxemia and its devastating effects, especially on the brain and spinal cord tissues, carbon dioxide control at a 3 per cent level, the efficiency of modern carbon dioxide absorbents, air conditioning with a wet bulb temperature at 75 F. or lower and so on are intimately presented. The author describes the construction and operation of two devices designed to save human life in sunken submarines, namely the "lung" and the rescue chamber. The four principal hazards to which professional divers are subject, namely asphyxia, blowing up, falling or being squeezed and caisson disease (or bends) are vividly set forth as well as the treatment given in the compression chamber. It is now generally accepted and recently has been roentgenologically confirmed that bends are due to gas saturation (nitrogen, also helium) in the tissues. Pure oxygen is now used in the prevention and treatment of bends. Decompression tables worked out for different depths and times of exposure have almost completely eliminated caisson or bend danger. Helium mixed with oxygen in the proportion of 4 to 1 has been found to have definite advantages over air as a respiratory gas for diving.

Plasma as Substitute for Whole Blood.—Elliott and his associates point out that the indications for blood transfusion suggest that the plasma fraction is of more importance than the cellular fraction. In shock, with and without hemorrhage, the

ready availability of blood plasma with no loss of time for cross matching has made it life saving in many instances. Blood plasma is probably even more satisfactory than whole blood because its diluent, dextrose and saline solution, is also capable of increasing blood volume whereas erythrocytes are not. Prepared plasma can be stored in any institution or physician's office in readiness for any emergency. It can be carried into the home and infused as readily as dextrose and saline solution. The loss of plasma protein from the circulation that follows extensive burns accounts for the decreased blood volume, the hemoconcentration and the circulatory failure. Transfusion of whole blood is beneficial and is a recognized therapeutic measure. However, the reasons for giving burned patients transfusions suggest that the beneficial effect is from an increase in the blood volume. The erythrocytes are above normal and there is no indication for increasing them. Plasma alone should be and in the authors' experience has been effective. If plasma is available, transfusion of whole blood may even be contraindicated. In severe infections complement in transfused blood is of utmost importance, but the protein of the blood plasma is more important. It not only maintains normal plasma protein, if given early and in adequate quantities, but also furnishes protein for the body's metabolic needs. In many of these cases the erythrocytes are normal. It is the authors' practice to infuse plasma until the erythrocyte count drops to about 4,000,000 and then to raise the blood count to normal with whole blood, resuming the use of plasma when this is accomplished. The need of the sick patient for protein, especially in an extended illness, is great. Maintenance of plasma proteins is much less difficult than their restoration; therefore plasma infusions should be started before the need is apparent. When protein intake is inadequate from starvation or other causes, with resulting hypoproteincemic edema, treatment must naturally be directed toward increasing the plasma proteins. Increased oral protein intake is the most satisfactory, but when this method is inadequate infusion of plasma is necessary. Dramatic clearing of edema is often observed if adequate plasma is administered. However, if any anuria exists a sudden increase of plasma proteins above the edema level may result in the withdrawal of water from the tissues to the blood stream at a rate faster than the kidneys can remove it from the circulation. When convalescent plasma is required and the donor and recipient belong to different blood groups, the erythrocytes can be removed and the incompatible plasma infused with safety.

Immunity to Poliomyelitis and Mouse Protection Test.
—According to Haas and Armstrong, the results of the mouse protection test, using eighty-three human serums and the Lansing strain of poliomyelitis virus, show that serum antibodies capable of neutralizing the Lansing strain of poliomyelitis virus are widely prevalent, especially among older individuals. The results secured with mice appear to be more trustworthy than those usually secured with monkeys, as mice are more uniformly susceptible. The results agree with those secured with human serums in monkeys. These considerations should render it possible to follow serum immunity in population groups from different localities and from infancy to adulthood and thus probably clarify many epidemiologic questions awaiting solution. More protection was shown by scrums of persons living in orphanages than by those of the same age group living in private urban dwellings.

Eclampsia.—Torpin and Coppedge encountered 350 cases of eclampsia among 16,000 live births to white women and 11,300 live births to Negro women. There was an incidence of one case of eclampsia to every ninety-six live white and sixty-one live Negro births. The majority of the cases among the Negroes occurred from the age of 15 to 19 and in the white from 16 to 20 years, inclusive. While the incidence is less in the older individuals of both races, the relative mortality among them is greater. Eclampsia occurred about twice as frequently in the primipara as in the multipara in the Negro, but only about one and one half times as often in the white primipara as in the white multipara. There was no evidence of cyclic variation in incidence over the twenty years during which the 350 cases occurred. Consequently a relation to weather, heat, humidity and atmospheric changes was not evident. The authors outline the following five point treatment of eclampsia: 1. Two Gm. of magnesium sulfate intravenously in sterile 10 per cent solution every hour as long as the systolic blood pressure is 160 or more; convulsions must be stopped, if mild, with paraldehyde and, if severe, with sodium phenobarbital. 2. A salt-free diet. 3. Intravenous injection of 3,500 cc. daily of a 5 per cent solution of dextrose in sterile distilled water while the patient is in coma, and oxygen and blood when indicated. 4. Absolute rest, with the foot of the bed elevated and constant duodenal nasal tube suction when the patient is comatose to prevent aspiration pneumonia. 5. When the condition improves or becomes stationary, induction of labor by rupture of membranes, if at term, or by catheter or bag insertion, if premature. Among the 183 Negro patients there were twenty-five deaths, a rate of 13.6 per cent. Of the 167 white patients twenty died, giving a mortality rate of 11.9 per cent. The stillbirth rate among the 200 recorded was 33 per cent in the Negro and 29 per cent in the white patients. During the time of the first half of the series veratrum viride was relied on to control convulsions, in the second half magnesium sulfate, with a resultant reduction in the general mortality.

Bismuth Arsphenamine Sulfonate for Lichen Planus.—Conrad and his co-workers treated cases of hypertrophic, generalized and localized lichen planus with bismuth arsphenamine sulfonate. The treatment consisted of injections of 0.1 Gm. of the drug twice a week. The usual minor reactions to the drug were encountered. The first few injections caused some discomfort, but with the continuance of treatment this was less frequent. In the usual case of three to four months duration relief of subjective symptoms is experienced after the fifth or

sixth injection and an apparent cure may be accomplished by fifteen or twenty injections. In the more chronic cases in which the disease has been present for months or years, and especially when the lesions have become hypertrophic, the number of injections to effect relief or apparent cure increases. In some cases the hypertrophic lesions begin to show evidence of involution after about the tenth injection and from that time on many show a definite tendency to decrease in size. The pruritus, while still present in patients with the hypertrophic type, definitely decreases and the patients usually are much more comfortable. This treatment was efficacious in the treatment of lesions of the mucous membranes. Among the authors' twenty-five cases the seven that involved the oral mucous membranes cleared up, but two relapsed. One case involving the glans penis failed to clear up. They conclude that, although the series is small and more work must be done, bismuth arsphenamine sulfonate seems to be of value in the treatment of lichen planus, especially in cases affecting the mucous membranes.

Chronic Constrictive Pericarditis.—Harrington and Barnes say the dominating symptoms of chronic constrictive pericarditis are dyspnea, ascites and edema of the legs. Dyspnea is present on exercise but absent when the patient lies flat. The cardiac output is reduced, the blood pressure low and the pulse rate uniformly accelerated. The condition usually is not associated with valvular heart disease and hence murmurs are absent. Calcification of the pericardium can be demonstrated by careful x-ray examination. If this confirmation is lacking, the electrocardiogram may yield diagnostic information. Anorexia, epigastric fulness and distress are an important subjective symptom. It probably is due to impaired function of the liver which they encountered in nine cases. In the advanced stage the venous pressure is elevated and the circulation time is increased. This distinguishes the condition from cirrhosis of the liver. The authors advise general anesthesia, preferably cyclopropane, because the operation may require considerable time. Their approach to the pericardium and heart in their nine cases was through the left side of the thoracic wall. They believe it is advisable to remove as much of the pericardial scar as possible from the ventricles, the right auricle and orifice of the inferior vena cava and to separate the scar from the diaphragmatic attachments of the right ventricle. The apex of the heart should be separated early in the operation. During removal of the pericardial tissue, when the pulse becomes very irregular, the operation should be interrupted and sponges moistened with warm saline solution should be applied. This permits the heart to regain or partially regain its former rhythm. The wound is closed in two layers with drainage at the lower angle. The inner layers of intercostal muscle and perichondrium are sutured to the posterior sternal fold with interrupted catgut sutures. The skin and outer layers of muscle are closed with interrupted dermal sutures. All patients are placed in oxygen cabinets or tents. Drains are removed in from thirty-six to forty-eight hours. Other postoperative measures are directed toward removal of body fluids and aiding the function of the liver. Intake of fluid is limited. Extensive calcification, associated with the fibrous constricting pericardium, was present in seven of the authors' cases. Of the two cases of fibrous pericarditis without calcification, one was proved to be due to tuberculosis and in the other tuberculosis was suspected but not proved. Three patients were cured, three were improved and three died three, four and twenty-nine days after operation. In only one of the

three fatal cases could any degree of improvement be expected. The damage to the liver was the most important factor in the patient's inability to recover. In the two other cases an appreciable improvement was improbable, for in one the myocardial degeneration with deposits of calcium extended through the heart muscle and in the other one the underlying etiologic factor was tuberculosis. The three cured patients presented the typical picture of Pick's disease and all had extensive calcification of the pericardium with constriction of the heart muscle. The results, after adequate removal of the constricting pericardium, exemplify the capability of the heart and liver to reestablish function if the damage has not been too great. The myocardium of all three was separated satisfactorily from the surrounding attachments.

Arsenical Dermatitis from Tobacco.—Barksdale calls attention to arsenical exfoliative dermatitis from tobacco. In recent years lead arsenate has been used widely as an insecticide on tobacco to kill the tobacco worm. Previously this worm was killed by hand. Tobacco is frequently sprayed with lead arsenate while it is growing. When it is placed on the market the lead arsenate remains on the leaf as a white powder and nothing is done in the redrying or manufacturing process to remove it. Consequently almost every cigaret on the American market today contains arsenic in an amount which might be dangerous to the person who does not have a high tolerance for it. The author has analyzed five brands of cigarets from packs bought on the open market. One or two cigarets were analyzed for its arsenic content, and then one or two more from the same pack were analyzed for arsenic after they had been smoked to an ash. The entire cigaret was burned up before the analysis was made. This analysis showed that an appreciable amount of arsenic is lost in the smoking process and so the person inhaling it could absorb it through the mucous membrane of the respiratory tract. The author reported five cases of arsenical exfoliative dermatitis from tobacco in the *Virginia Medical Monthly* (66:660 [Nov.] 1939). He cites several more cases. The Gutzeit arsenic test was used for the analysis of the cigarets as well as for the examination of the body fluids of the patients. The cases with exfoliative dermatitis and a high blood arsenic content cleared up on practically no treatment other than the removal of tobacco. It is thought that exfoliative dermatitis is an allergic phenomenon. The majority of people can use tobacco containing arsenic because they are not sensitive to it, just as the majority of syphilitic patients can take arsphenamine without harmful results. The author thinks that patients develop exfoliative dermatitis from the arsenic in the tobacco because they are hypersensitive to it. The allergic state probably causes a spasm of the arterioles, thereby preventing normal excretion with the resulting retention in the body. The clinical observation that these patients have shown much improvement when the tobacco has been removed is probably the most definite proof that the latter is the cause of their condition. The blood of patients with exfoliative dermatitis from other causes apparently does not contain arsenic even though they are heavy smokers. The blood of normal individuals, even though they are heavy smokers, does not contain arsenic. The author recognizes that the number of cases reported is not sufficient to warrant any definite conclusions.

Klippel-Feil Syndrome.—According to Hadley, the symptom complex of short neck, growth of the hair low down on the neck and limitation of head movements which now bears the

name of the Klippel-Feil syndrome is found with congenital anomalies of the cervical spine. He presents three cases. The first patient, a man aged 48, was operated on at the age of 20 under a mistaken diagnosis of congenital torticollis. The deformity persisted. There was a marked cervicodorsal lateral curvature to the right and limitation of the head movements in all directions. X-ray examination showed a fusion of the second and third cervical vertebrae and an incomplete development of the left half of the sixth, forming a wedge-shaped vertebra. There was an upright cervical rib present. The second patient, a woman aged 37, was noted to have an abnormally short neck with a low margin of the hair. She had considerable lack of motion of the neck with the head tilted to the right. X-ray examination showed that the first and second, as well as the fifth and sixth, cervical vertebrae were fused. There was also a spina bifida occulta of the sixth and seventh cervical and first four thoracic vertebrae. The third patient, a woman aged 44, complained of pain in the left shoulder which was higher and closer to the vertebrae. There was marked limitation of movement of the left shoulder. X-ray examination showed a typical Sprengel's deformity with articulation of the left scapula to the first, second and third thoracic vertebrae. Spina bifida occulta of the first, second and third thoracic vertebrae was present and a scoliosis with the convexity to the left. A complete x-ray study is essential for the exact diagnosis of the deformities of the spine. Anterior oblique films, both right and left, are taken at the level of the fifth cervical and an anterior posterior film through the mouth. The cephalic extremity and its articulation giving a complete image of the atlas can be roentgenographed through the nasal cavity or anteroposteriorly with the central ray 1 cm. above the point of the nose and the lateral view through the center of the lobe of the ear. The distal extremity is best taken by an anteroposterior film through the center of the first dorsal. The remainder of the spine should also be roentgenographed for possible associated abnormalities, as various forms of numerical and morphologic anomalies may be found. The typical Klippel-Feil syndrome is due to a numerical reduction of the cervical vertebrae. With this may be associated a spina bifida anterior, which causes usually a cervical dorsal curve with the convexity generally to the left and with a sharp inflection at the summit. Spina bifida posterior usually causes an abnormal neck having an inclination of the head to the side and an elevation of the corresponding shoulder. An atlas-occipital fusion often presents a form resembling spasmodic torticollis if the disturbance is asymmetrical or, if symmetrical, resembling Pott's disease. In the clinical study the shortness of the neck bears a relation to the gravity of the malformation and the head in severe deformities appears to repose directly on the trunk. A round back may be present, owing to the absence of or alternation of the normal cervical curve. Accessory signs are scoliosis, disproportion of the length of the arms and the trunk and low placement of the ears; there is ascension of the skeleton in relation to the skin. An elevation of the scapula is a striking accompaniment.

Malignant Lesions of Small Intestine.—According to Mayo, 108 cases of surgical malignant lesions of the small intestine were encountered at the clinic from 1907 to 1939 inclusive. This represents 1.5 per cent of the surgical malignant lesions of the stomach and 1.4 per cent of the surgical malig-

nant lesions of the large intestine observed during the same time. The jejunum was affected most frequently. The ratio of multiple lesions to single lesions in the small intestine was about the same as that in the large intestine. The vast majority of these lesions occurred among patients whose average age was 52.6 years. This pathologic change occurred about two and one half times as frequently among men as among women. The actual or tentative diagnosis of a malignant lesion of the small intestine was made in 25.7 per cent of 101 cases. It seemed to have been somewhat easier in cases in which the growth occurred in the jejunum and duodenum. The two main features which stood out were recurrent attacks of intestinal obstruction with intercurrent relief and anemia, weakness and fatigability. A careful history will often reveal the fact that these later symptoms antedate the gastrointestinal complaints. Loss of weight, although constant in the late stages, is inconstant early in the disease, as is also constipation. One could assume that, the higher the lesion is in the intestinal tract, the more quickly the symptoms would present themselves. This is not the case. Barium sulfate orally for x-ray examination in the presence of obstruction in the small or large intestine is inadvisable. With the advent of the Miller-Abbott tube for intestinal decompression, barium sulfate in fine solution could be used and the portion of intestine proximal to the site of obstruction can now be satisfactorily cleansed prior to operation, but close attention and careful effort by competent physicians are essential. The roentgenogram, when it signifies the presence of a lesion of the intestine, reveals evidence of a narrowing or filling defect of the intestinal lumen at the site of the lesion and a compensatory widening proximal to the obstruction. The retention of barium sulfate in the small intestine for more than eight hours should arouse suspicion of a pathologic lesion and stimulate further effort toward localization of the lesion, if compatible with the condition of the patient. Surgical procedures in the 108 cases were carried out by eighteen surgeons. When possible, resection and reestablishment of intestinal continuity was the operation of choice and the next choice was a palliative procedure and exploration. Closure was employed only when the other two procedures were not applicable or were deemed to be without benefit. Resection (42.4 per cent) could be accomplished most frequently for lesions of the ileum, palliation (41.3 per cent) such as gastro-enterostomy was the most usual procedure for malignant lesions of the duodenum and exploration alone was possible in 16.3 per cent. The typical malignant lesion of the small intestine is an adenocarcinoma, much the same ring, constricting type that is frequently observed in the distal half of the colon. Leiomyosarcoma made up a little less than 10 per cent of the malignant lesions in this region. Metastasis first involves the lymph nodes of the mesentery, then the peritoneum, liver, lungs, long bones and dura mater. Of eighty-five patients operated on prior to January 1938, eighty-three were traced and of these twenty-five, or 30.1 per cent, survived for more than a year. Of sixty-six patients operated on prior to January 1934, sixty-five were traced for five years and eight, or 12.3 per cent, survived for five years or more.

Renal Cortex Infection.—Baumeister and McCutchan stress the importance of recognizing staphylococcal infections of the renal cortex. They outline a new clinical test for differentiating the condition from other kidney infections. Sulfanilamide is efficient in the treatment of pyelitis and pyelonephritis, especially cases due to *Bacillus coli*, *Bacillus proteus* and staphylococci. Sulfamethythiazole is the most efficient and least toxic of the drugs used thus far against staphylococci. A sterile urine is nearly always produced in from two to four days, provided the infection is not complicated by malformation, neoplasm or stone in the urinary tract. These sulfamide antiseptics have no effect in staphylococcal cortical infections of the kidney. There is a septic thrombosis of the glomerulus and the beginning of the renal tubule. The blood supply of these areas is cut off and antiseptics cannot reach them. In pyelonephritis no such state of affairs is present, the blood supply being relatively intact. Some other common conditions from which the differential diagnosis may have to be made are appendicitis, intra-abdominal

abscesses due to ruptured appendix, gynecologic inflammations, perforated gallbladder, perforated diverticulitis, perforative carcinoma of the colon and renal and ureteral calculi. The matter of treatment is highly controversial. These patients must first have supportive therapy. Their water and electrolyte balance must be kept at the proper levels. A good percentage recover spontaneously. If the patient does not show definite improvement in a few days, an operation should be performed before the condition becomes too severe or a perinephric abscess forms. Decapsulation is unnecessary if the abscesses lie close to the surface. Following mobilization of the kidney, a gauze pack is wrapped around it and kept soaked with a solution of 25 per cent glycerin in saturated magnesium sulfate solution. The patient is kept on his back with an electric heat pad applied continuously. After a few days the pack is withdrawn and rubber drains are placed around the kidney. Moist surface packs are applied.

Head Injuries.—Meredith presents a statistical survey of 391 unselected cases of acute head injury. The state of consciousness is the most important single factor in evaluating the status of any patient with an acute head injury. X-ray examination of the skull of all patients rendered unconscious is imperative and such patients should be hospitalized, at least overnight, or sign a release. Direct palpation and inspection of the underlying skull in all lacerations of the scalp is important to eliminate or establish compound depressed fracture. Lumbar puncture is necessary only in about 15 per cent of head injuries. Dehydration is of little value and morphine is interdicted except for patients with no surgical lesion who remain restless under milder sedation. Alcohol should be disregarded as a factor in the patient's condition unless blood alcohol studies are made. The head should be elevated unless the patient is in shock or much mucus is present in the tracheobronchial tree. Sulfanilamide is of great value for cerebrospinal fluid leaks from the cranial orifices. Nasal tube feedings should be more widely used for any unconscious or semiconscious patient. Hyperthermia should be combated promptly. Operations in head injury cases include those for elevation of depressed skull fractures, diagnostic burr openings and evacuation of clots. Subtemporal decompression is rarely performed today. Occasionally repair of a cerebrospinal fluid leak through the nose is required. An increasing stupor, with signs of increased intracranial pressure, calls for operative intervention. Of the 391 patients with acute head injuries, thirty-three died, a mortality of 8.4 per cent; of forty-two patients operated on ten died, and of 124 with skull fractures twenty-one died. Eighty-seven of these 124 patients had no associated injuries and only eleven died, but of the remaining thirty-seven who had associated injuries ten died. Likewise the mortality for all types of head injuries with associated injuries was 12 per cent as compared to 6.8 per cent of all types of head injuries with no associated injuries. The associated injuries were fractured pelvis, spine or femur and abdominal or chest injuries.

Local Treatment with Azosulfamide.—Smith reports five cases in which azosulfamide was used locally. The cases were pneumococcal empyema, abscess in the gluteal region, varicose ulcer, perineal ulcer and a large raw surface on the chest, neck and arms resulting from a severe burn. The drug had antibacterial, deodorant and stimulating action in these cases. Toxic effects did not occur. From these results (and in twenty-five other cases) and from the literature it may be concluded that azosulfamide has a powerful antibacterial effect when in contact with infected tissues. This treatment may be of great value in war wounds and injuries, all of which are certain to be contaminated. The deodorant and stimulating action of the compound may be produced by the dye substance contained in azosulfamide.

Chronic Meningococcal Septicemia and Cerebrospinal Fever.—Stott and Copeman state that chronic meningococcal septicemia is not well known in England. The meningococcus may inhabit the blood stream for weeks, months or even years and causes an illness which is so characteristic that it should be as readily recognized as meningococcal meningitis. Recent experience in France has led the authors to believe that chronic meningococcal septicemia is not uncommon but is often overlooked because of a superficial resemblance to other conditions. They present details of seventeen out of twenty-seven such cases they have encountered recently. Although the isolation of the meningococcus from the blood is the only certain method of diagnosis, chronic meningococcal septicemia is so characteristic that bedside diagnosis is simple. Early diagnosis is important, as grave complications may arise. Early diagnosis is also important because sulfapyridine is a prompt and effective remedy. The onset of the disease is usually sudden, with fever, chilly feelings or a rigor, severe headache and severe migratory joint and muscle pains. Within a few days a characteristic rash appears. The lesions are usually pink or red macules, papules and nodules. The papules and nodules are sometimes painful. The rash is most profuse on the limbs and on the back of the

Treatment of Trichomonal Vaginitis. M. L. Pérez, N. Arenas and O. Blanchard.—p. 1532.
Periods of Fecundity and Infecundity of Women. A. S. Coatz.—p. 1544.

Trichomonal Vaginitis.—Pérez and his collaborators found in a group of women cared for in the social maternity hospital of Buenos Aires trichomonal vaginitis with pruritus and discharge, alone or in association with urethritis, cystitis and intertrigo, in 32 per cent of nonpregnant women and in from 50 to 70 per cent of pregnant women. The authors report satisfactory results in a group of 167 women with intravaginal insufflation of a powder of acetarsone or of silver picrate. The insufflations are given at intervals of from five to seven days, during which vaginal douches and coitus are interdicted. The treatment is continued one or two months, involving a total number of from five to seven insufflations. The arsenical treatment is preceded by painting the vagina with a solution of picric acid 1 Gm. in 100 cc. of distilled water. This is allowed to dry before insufflation is administered. The insufflation consists of 2 Gm. of acetarsone in 4 Gm. of kaolin. The vaginal orifice is occluded with gauze all around the pulverflator and the powder is blown all over the vaginal wall. The silver insufflations are given in the amount of 0.5 Gm. of silver picrate in 5 Gm. of kaolin. In stubborn cases acetarsone is given by mouth. Silver suppositories may be added during the first week of the reported trichomonal vaginitis was controlled by arsenical treatment in 150 cases and by silver picrate in seventeen. Satisfactory results have persisted for from three months to two years after discontinuation of the treatment in the majority of the cases, and for less than three months in a few cases which are still under observation.

Treatment and Etiology of Nocturnal Enuresis in Children. S. I. Vaynbaum.—p. 32.

Nocturnal Enuresis in Children.—Vaynbaum treated 122 patients with nocturnal enuresis. The patients were examined by an ophthalmologist, a pediatrician, a laryngologist and a neurologist in order to exclude cases of myopia, tonsillar infection and helminthiasis. There were twenty-one patients of ages up to 6 years, seventy-nine up to 10 inclusive, twenty-two above 10 and below 15. The treatment consisted of daily injection into the gluteal muscles of a 25 per cent solution of magnesium sulfate in doses beginning with 0.5 cc. and increasing gradually up to 3 cc. Enuresis became less frequent after the first few injections and did not occur after from ten to fifteen injections. There were no untoward reactions. The patients were followed up for from six months to one year. All except four were cured. Three patients with congenital syphilis. They were given antisyphilitic treatment, at the termination of which enuresis had disappeared. The second group presented a number of organic, dystrophic alterations and a generally retarded development suggesting that the cause of enuresis here was an increased irritability of the detrusor muscle and weakness of the urinary bladder. The author does not exclude the possibility of congenital syphilis in this group as well. The rationale of magnesium sulfate therapy is based on the depressing effect of the drug on the sensory nervous system, the peripheral nervous system and the sensory nerve fibers. The treatment of enuresis calls for strict individualization because of the varied etiologic factors. Magnesium sulfate therapy appears to be successful in cases in which there is increased irritability of the detrusor muscle and spastic bladder.

trunk. Successive crops appear, often with the rise of temperature, and each crop lasts for a few days, leaving a slight brownish discoloration. If untreated with the sulfonamides the fever persists for weeks, months or even years. The rise of temperature may be accompanied by chilly feelings or a rigor and a fresh crop of cutaneous lesions. The chief complications are meningitis and infective endocarditis; nephritis and acute epididymitis also occur. In one of the authors' patients acute epididymitis developed. This disappeared rapidly with sulfapyridine treatment; one patient had a mild peripheral neuritis in the legs with loss of ankle jerks and sensory disturbances, and a few complained of a residual painful stiffness of muscles after all signs of active infection had disappeared. The history of two patients with cerebrospinal fever suggested chronic meningococcal septicemia for from two to four weeks before the onset of meningitis. Sulfapyridine orally in moderate doses terminated the disease in fifteen cases within twenty-four hours. There was a rapid return to health. The authors' experience with the disease has led them to believe that this type of meningococcal infection is common whenever meningococcal meningitis becomes prevalent in a community. The cases recorded were seen within a period of nine weeks during the prevalence of cerebrospinal fever in the British Expeditionary Force.

Functional Relations Between Spleen and Stomach.—Gipperich reports observations on four patients with splenomegaly due to venous stasis and Banti's disease. The patients complained for some time about gastric disorders and a dull pain in the left abdominal quadrant, worse after meals. There were disturbances in the amount and the chemism of the gastric secretions, which were in direct proportion to the acuteness of splenomegaly and which were controlled by splenectomy. There after the operation the amount of total secretion and total acidity, which were deficient, increased over normal figures and became normal in a few months. The chemical constituents of the gastric juice became normal after splenectomy. The author believes that the hypophysis maintains a close hormonal relation with the spleen on the one hand and with the secretory functions of the stomach and the chemistry of the secretory products of the other. Splenomegaly interferes with the production of hypophysial hormones concerned with the functions and chemism of the gastric secretion. Splenectomy is followed by an early hypophysial reaction with overproduction of such hormones. When the hypophysial reaction is over, the hormonal relations between the hypophysis and the stomach become reestablished with consequent normal gastric secretion and chemism.

RESPONSIBILITY FOR CHOOSING INTERNS AND INTERNSHIPS

WILLIAM DOCK, M.D.
SAN FRANCISCO

This year the Commission on Graduate Education published its report,¹ in which the history, present illnesses and prognosis of internship and residencies were thoroughly reviewed. Here arguments for and against including a year of hospital service in the requirement for the degree of Doctor of Medicine were presented. However, two more aspects of the responsibility of medical schools toward the appointment of interns deserve study, since they apply not only to the fifth year problem but to present defects in the appointment of interns throughout the whole country.

Certain undesirable situations arise whenever the dean or the administrative office of a medical school is actively concerned with obtaining appointments for senior students. These bad effects are most strikingly seen when the fifth or intern year is required for graduation. There the school must intervene not merely to supervise the choice but actually to guarantee the placing of the student. If the dean or a faculty member or committee has to guide the student or even help him to secure an internship, the school to a greater or lesser degree must appear as a petitioner for favors from hospitals. Beggars cannot be choosers and certainly cannot be critics, so that the school or its representative must pass lightly over the defects of the institutions kind enough to accept the eight or ten students at the bottom of the class. Also, once the school has recommended a man for internship and has begun to count on placing its men in certain institutions, it will find reasons for not allowing any senior student to fail. To do so would put it in the position of reporting, a few weeks before the service begins, that Mr. X, recommended as a competent man in November, has failed to complete his fourth year. This would jeopardize the chance of placing men in that hospital in the future. Hence a distinct drop occurs in the work of the less diligent third or fourth of the senior class in schools where, because of custom or the fifth year rule, the student relies heavily on faculty help in securing his internship and preventing his failure.

It would be a decided tonic to the morale of medical students and of deans and committees on promotion if the school and its staff confined themselves to supplying students with a list of recommended internships and sending hospitals a record of scholastic accomplishment and relative class standing of each student who applied for internship. No personal recommendations should be supplied in an official way, and hospitals

should demand personal interviews or reports from reliable and disinterested third parties, preferably practitioners in the community who were former interns or colleagues of men on the hospital staff. The whole responsibility for choice and attainment of internship should rest on the student, who should realize by the end of his second year that the sort of internship he may look forward to depends on his scholastic record and the good impression he makes on staff members of the hospital he hopes to enter.

There is another evil consequence of medical school solicitude over placing its students in hospitals which is also most apparent where the fifth year is required for graduation. This is the tendency to fill with its own graduates most of the positions in the services which the medical school controls and uses for instruction. This practice has a pernicious effect both on the interns and on the undergraduates. It may diminish the effective competition for positions and lessen the zeal of the best members of the class, to whom these positions normally go, since they have little to fear in the way of outside competition and their relative positions are pretty well determined by the third year. It surely lessens the drive and lowers the morale of the interns, who do not start off in a fresh environment among new associates, all anxious to establish a good record for themselves and for the school from which they come. Instead they run on in the same rut and with the same "gang." With the increasing participation of students in the life of the wards, clinics and operating room, the interns and residents have become even more important than the chiefs and staff members in molding the habits and attitudes of undergraduates. From the staff they pick up tricks of speech or of thought, but from the interns they absorb the working methods and the reactions to patients and to investigation which will determine most of their professional conduct. The selection of interns and residents with a view to getting the best possible men and having them work under conditions which will bring out their finest efforts and behavior is therefore the most important duty of the staff of a teaching hospital, not merely that the opportunity for graduate teaching should not be dissipated but in order to have undergraduates live in the best possible professional atmosphere. The necessity for selecting the best interns and for assembling a group trained in various schools and constantly on their toes is so urgent that it should not be weakened by pleas to absorb as many local graduates as possible and diminish the chore of placing an entire class. To win the gratitude of shy or backward seniors by helping them avoid the responsibility for finding hospital positions or moving into a strange environment, one must accept responsibility for lowering the whole level of graduate or undergraduate work.

The limitation of enrolment, the increase in laboratory and ward work and the emphasis on hours of

From the Stanford University School of Medicine.

1. Graduate Medical Education, University of Chicago Press, 1940.

credit rather than on learning have all contributed to slow down or stop entirely the free movement of medical students from one school to another. The changes of the last forty years have steadily diminished the differences between the work of the last two years of medical school and the first year of internship. Since there can be too much even of good things and since it is possible that "one good custom should corrupt the world," it is desirable that most students should not intern in the wards where they worked as juniors and seniors but should see new methods, hear new teachers and work with new companions. Any change in methods of appointment of interns which increases the movement of medical students from one center to another at this stage of their development is certain to raise the level of internship in hospitals having university connections, and gradually this will have an effect on all hospitals. Customs which increase inbreeding of the hospital staff and make circulation of young medical men more difficult are truly harmful.

The first responsibility of the universities is to improve the internships they control; they can do little to raise the quality of services without medical school contact except by example and certainly not by trying to control the work or make the intern year an undergraduate exercise. The fifth year problem might well be left in the hands of the licensing boards, since it certainly is better to have at least one year of post-graduate work before taking examination for licensure. It must be granted that the average medical graduate of today is far better equipped to practice than the men trained by lectures and recitations a generation ago; that there is really less need for internship before graduation than there was when the fifth year requirement was first imposed. It is proper to commend the wisdom of those licensing boards which insist on a fifth year, but the protection of the citizens should rest with these boards and not be left to the haphazard practice of medical schools, of which only thirteen now have this requirement. Forty-four per cent of the states but only 17 per cent of medical schools make internship mandatory.

The improvement of internships in hospitals without medical school connections can safely be left to the national societies, whose influence has already been so powerfully and effectively applied. Probably the most fruitful change the medical schools could put into effect would be to limit to one half or less of the total number that group of interns chosen from local graduates. Students should be encouraged to visit or do ward work in other hospitals during the summer after the junior year in order to have a better basis for evaluating and to pave the way toward securing an internship. There should also be a more uniform time for appointing interns, no *sub rosa* commitments before this date and a strict avoidance of "trading" between medical schools, so that there would be the least possible pressure to seek to obtain interns or internships by "deals."² It

is desirable to give the maximum freedom of choice to the student seeking hospital appointment and to the hospital staff selecting men for internship. As long as the university attempts to guide or assist the student, this freedom of choice is restricted and the result is harmful to students and to medical schools.

THE CARE OF THE PREMATURE INFANT

ETHEL C. DUNHAM, M.D.

AND

JESSIE M. BIERMAN, M.D.

WASHINGTON, D. C.

Special studies have shown that at least 5 per cent of all infants born alive are born prematurely.¹ This means that more than 114,000 infants were born prematurely in 1938. In the same year more than 31,000 neonatal deaths were reported by the United States Bureau of the Census as directly due to premature birth. The neonatal mortality rate from this cause in 1938 was 13.8 per thousand live births. These figures indicate the importance of the problem at the present time.

The earliest recognition in this country of the role that premature birth plays in infant mortality appears to have been an address on infant mortality given before the American Medical Association in 1857 by Reese.² He stated: ". . . we include among the infant mortality all those recorded interments marked as stillborn and premature births, the extent of which, and especially their amazing increase, constitutes one of the most revolting and yet one of the most important features of our inquiry and one which cannot be contemplated without horror."

From 1857 to the turn of the century, reports with regard to premature infants dealt largely with the viability of these infants, including several reports³ of survival of infants of less than six months' gestation, and of one weighing 1¾ pounds (794 Gm.) at birth.⁴

EARLY RECOGNITION OF CRITERIA OF CARE

Among the earliest papers dealing with methods of care of premature infants was one by Bartlett⁵ in 1827. He referred to the types of incubators in use in Russia and in France and described his "water-jacket warming crib," made large enough to hold triplets! In the same year Taylor⁶ reviewed foreign literature dealing with the care of premature infants and decried the custom of putting on "the usual clothing." He also discussed the relative merits of feeding premature infants by tube and with a spoon.

2. In view of the importance of having the best possible intern services to establish the correct atmosphere in wards where undergraduates are being trained, it is desirable that these teaching services should have first choice of interns; this will benefit all hospitals by raising the level of undergraduate training. At present many excellent students who desire such services are lured away by other hospitals which offer the security of very early appointment. It is to be hoped that all the agencies concerned with better medical education will work out methods by which all hospital appointments will be offered on specified dates and that the first offers will be limited to teaching institutions. For example, if the hospitals' first choice of appointments were mailed November 15, the acceptances of the first group of interns could be received and the second choice appointments sent out by December 1 to men who had indicated they were still available; the third choice could be made by December 15. Under such a system the student would take the most desirable service open to him, and the hospital would get the staff which its reputation merited.

According to Ryan⁷ in 1889 "the best food is, of course, the milk of the mother if she be healthy." Only one dissenting opinion was found, that of Adriance,⁸ who contended that the mother's milk after premature labor is not suitable for premature infants because it has a higher protein content than that of milk of women whose labor is at term.

In 1890 Southwick⁹ referred to an incubator first devised by Cr  d   about 1850, describing it as "essentially a bath tub with hollow walls filled with hot water." He reported that this type of incubator was in use in the Boston Lying-In Hospital but added "I am informed that it fails to give perfect satisfaction. The heat comes too near the child without being diffused and the ventilation is defective."

Voorhees¹⁰ in 1900 described the Lion incubator, a French type, and stated that it could be disinfected, that there was provision for ventilation, for moisture and for measurement of the moisture with a hygrometer, and for filtration of the air. He pointed out, moreover, that the infant was visible through glass doors and could be tended without removal from the incubator. All these points are stressed at present in discussing the proper conditions under which premature infants should be cared for in incubators.

From this brief review of the early literature of this subject it can be seen that the three criteria for care of the premature infant now considered fundamentally important were so recognized many years ago. Early efforts, like those of today, were directed toward keeping the infant warm, protecting him from infection and feeding him properly.

PROGRESS IN METHODS OF CARE

In the intervening years, progress has been made in developing methods for care of premature infants. Outstanding contributions are the improvement of incubators by the use of electrical heating devices, the development of air conditioning and air sterilizing, the use of parenteral fluid and blood transfusion, the use of oxygen to overcome asphyxia, and the development of individualized technics for care as a means of preventing infection. Exact assessment of certain methods of care, including feeding, is somewhat difficult, however, because studies designed to test them have not been controlled for such factors as birth weight, gestational age, race, sex and economic status. Furthermore, evaluation of one particular aspect of care, such as feeding, is complicated by the fact that the contribution of other factors to the welfare of the infant such as nursing care and environmental conditions cannot be separated from the effect of feeding.

It might be thought that the principle underlying the care of premature infants should be simulation, as far as practicable, of intra-uterine conditions, but this is obviously an impossible goal. It becomes our problem, then, to devise methods of care which serve to help the infant maintain his physiologic mechanisms inde-

pendently in the presence of changing external conditions. This in turn calls for increased knowledge of the physiology of premature infants so that we may rationally determine the environment and the feeding which will be suitable for him with his limited powers of adaptation.

Maintenance of a constant body temperature depends on a balance between heat production and heat loss. The common nursery practice of wrapping a premature infant like a mummy may, it is true, prevent excessive loss of heat, but it is an effective means of preventing muscular movements which increase heat production. After all, the fetus in utero moves freely after the fifth month and is prepared to do so after birth.

Some type of heating device must be used in caring for premature infants to prevent loss of heat from the skin. A great variety of "incubators" have been produced in recent years, both commercially manufactured and home made. Definite advance has been made in their construction and operation, and clinical

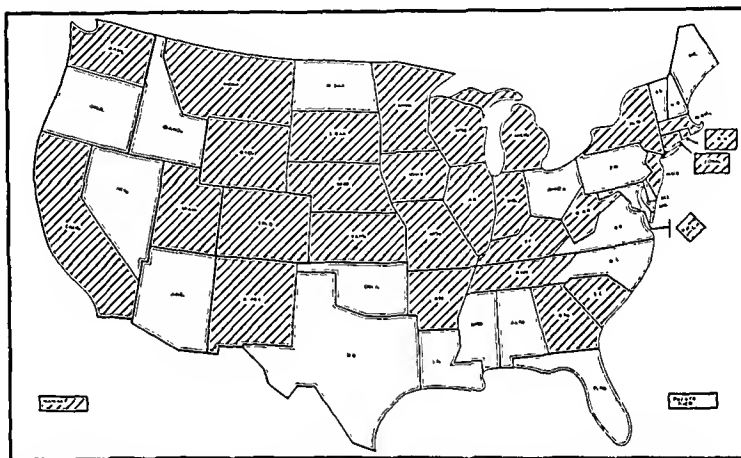

Fig. 1.—States in which the State Health Department has reported to the United States Children's Bureau some type of program for care of premature infants during the fiscal year 1939-40 (26 States, Hawaii, and the District of Columbia), under Title V, Part I, Social Security Act.

Fig. 1.—States reporting some type of program for care of premature infants.

experience has proved their value in raising and maintaining the body temperature of the premature infant. It should be pointed out, however, that further progress in this direction depends on further knowledge of the optimal environment for premature infants of varying degrees of maturity, on the development of definite standards for construction and operation of incubators and on more exact clinical evaluation of their effect on the infant.

The fluid and caloric needs of the premature infant have been fairly well established. After the first week or two or until his manifestations of hunger become a guide, they can be met by the daily administration of approximately 150 cc. of fluid and 120 calories per kilogram of body weight (2½ ounces and 55 calories per pound).¹¹ During the first week of life the fluid and caloric requirements are less.

IMPORTANCE OF BREAST FEEDING

That human milk is the ideal food for the premature infant is almost universally accepted. The fact remains that long-standing clinical observations support this view. It should be pointed out, however, that pre-

mature infants will thrive when fed suitable cow's milk mixtures, but in general the safest and most economical food for these infants is breast milk.

DIET OF THE LACTATING MOTHER

The quantity and quality of breast milk are dependent chiefly on the health and diet of the lactating woman, but there is good reason to believe that more effective efforts are being made to provide adequate diets for lactating cows than for lactating women.

Studies of diets of city and village families in relation to size of income and number in family have shown that in each income class the larger the family the fewer are the protective foods that are purchased.¹² Lactating women need these protective foods in larger amounts than nonlactating women. Human milk will obviously be deficient in certain elements unless special efforts are made to educate lactating women with regard to food purchases and to the use of protective foods (such as milk, tomatoes and citrus fruits, leafy green and yellow vegetables, and eggs). If for economic reasons it is not possible for lactating women to secure these foods in sufficient quantity to protect their own health as well as that of the infant, ways must be found to supplement their diets. It is, of course, well known that even if the nursing mother's diet is adequate the premature infant's food will need to be supplemented in certain respects, for example with vitamin D and iron, and probably with vitamins A, B₁ and C also.

Vitamin D should be given to the premature infant before the end of the second week of life in dosage larger, perhaps by three or four times, than that usually recommended for full-term infants. It should be given in a concentrated form and one which contains adequate amounts of vitamin A also.

The premature infant's requirement for vitamin C can be assumed to be at least that of the mature infant.

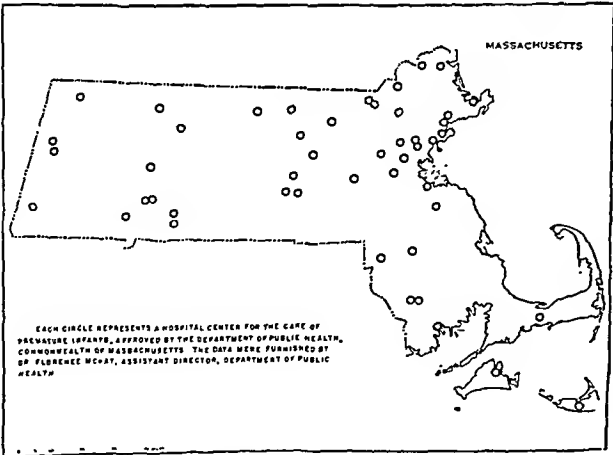

Fig. 2.—Location of hospital centers for care of premature infants.

For the latter Smith¹³ reports that "the recommended allowances fall within the comparatively narrow range of . . . from 20 to 50 mg. daily after the first few days." She quotes Ingalls' estimate that between 500 and 1,000 cc. of breast milk "of good quality" provides the equivalent of from 20 to 40 mg. of ascorbic acid daily. Since the premature infant can take but small

amounts of breast milk and since often he receives breast milk from some woman other than his mother, or pooled breast milk which has been pasteurized or boiled, there will certainly be need for additional vitamin C. To meet the full requirement at least 40 cc. of orange juice would have to be given before the second week of life. Obviously vitamin C will have to be given to premature infants in concentrated form until they are able to take the required amount of orange juice.

Cowgill¹⁴ suggests that the full-term newborn infant's optimal or perhaps minimal requirement for vitamin B₁ is 80 international units a day. Even if the mother's diet is considered adequate in vitamin B₁ there is no assurance that her milk will provide adequate amounts of vitamin B₁ to meet the needs of the premature infant. Supple-

ments of vitamin B₁ have been reported to affect favorably the premature infant's general condition.

Many other needs of the infant handicapped by premature birth could be pointed out. Mention must be made of the fact that neither human nor cow's milk contains sufficient iron to meet the premature infant's need. Although it may not be possible to prevent the development of anemia in premature infants, the condition can be ameliorated by the administration of iron and later by the addition of iron-containing foods to the diet.

Recognition has been given to most of these dietary needs of the premature infant as well as the dosage and the age at which dietary supplements should be given. It is our responsibility to see that they are administered at the proper age in dosage and form suitable to the needs of premature infants and that they are made available to all premature infants.

There are other needs of premature infants about which less is known, for example the need for certain hormones, gland secretions and antibodies which are transmitted from mother to full-term infant. Attempts have been made to provide some of these substances to premature infants but the evidence presented as to their efficacy is unconvincing in many instances and further study is needed.

The burden of responsibility to supply knowledge with regard to well established methods of care of premature infants has been greatly increased in recent years because there has been greater demand for this knowledge and wider application of methods of care. Unfavorable social and economic conditions are also being recognized more widely as barriers to adequate care of premature infants in the home, and advice and assistance given by social workers and public health nurses are recognized as important factors in saving the lives of premature infants.

COMMUNITY PROGRAMS

In addition, standards for equipment and care of premature infants in hospitals and homes have been set up and the acceptance of them has extended. Last, but not least, community organization for care of premature infants has been developed on a wide scale in the last few years.

An example of a citywide plan for care of premature infants is that which has been in operation for about five years in Chicago. During this period the mortality rate from premature birth under 1 month has been lowered 31 per cent (from 13.7 to 9.4 per thousand live births).¹⁵ State organization for care of premature infants has been developed widely during the past five years when funds have been available to the maternal and child health divisions of the state health departments under the terms of the Social Security Act, title V, part 1, administered by the Children's Bureau.

According to the most recent reports received by the Children's Bureau, twenty-eight states, the District of Columbia and Hawaii have already made or plan shortly to make special provisions for the care of premature infants as shown in the map (fig. 1). The plans vary in scope from a plan confined to one area, such as a rural county, or to one aspect of care such as provision of a warm bed, to a statewide plan such as that in progress in Massachusetts. In this state forty-eight centers for care of premature infants have been established in hospitals throughout the state, as shown in figure 2.

Some of the states include in their plans educational programs and the extension of medical and nursing services. In the development of these plans the steps usually taken by the state health departments have been first to study, often in cooperation with the state medical societies, the influence of prematurity on the infant mortality rate of their state and then to make a survey of existing provisions for the care of prematurely born infants in various parts of the state. The Social Security Act directs that rural areas and areas in special need shall receive particular attention, and most states have found existing provisions for care of premature infants in these areas very inadequate.

The educational programs have included the provision of special training in the care of premature infants for members of health department staffs, both medical and nursing, at such centers as the Sarah Morris Hospital in Chicago and the Lying-In Hospital in Boston. The staff member receiving the training, usually a supervising nurse, is thus enabled on her return to teach modern methods of care to the public health nurses of the health department and also to advise the nursing staffs of hospitals in a consultative capacity. Pediatricians on the staffs of state health departments have carried on educational programs for local health officers and have secured the interest and cooperation of practicing physicians in providing improved care for premature infants. Care of the premature infant has been discussed in postgraduate courses for physicians in a number of states. General educational programs have enlisted the interest of the public in providing better facilities for premature infants.

In addition to these educational efforts, which are of course basic to the success of any program, the state health departments have provided or extended the ser-

vices of public health nurses. These nurses assist practicing physicians in caring for premature infants in their homes where necessary, and also teach members of the family the special methods of caring for the infant. State health departments in a number of states give assistance to administrators of hospitals in planning for better facilities for the care of premature infants and in teaching their nurses modern technics in this field. In a few states they have provided qualified pediatricians for consultative services to rural physicians.

That provision of special beds has been effective in favorably affecting the welfare of premature infants directly and indirectly is shown in the bar diagram (fig. 3) taken from the report of the Cattaraugus County Department of Health. It can be seen that in each of three years the number of beds increased and the mortality of premature infants decreased. Obviously there were other factors of improved care that accompanied the provision of beds.

As a result of these special programs, state and local, closer cooperation has been brought about between hospitals, practicing physicians, public health nurses and health and welfare departments. These services have already proved their worth in improving the chances for life of premature infants born at home.

From the annual reports of the Bureau of the Census the trend of mortality from premature birth under one month for the United States as a whole has been charted (fig. 4). It can be seen that the mortality rate decreased only 12 per cent in the twenty year period

Fig. 4.—Trend of neonatal mortality from all causes and from premature birth, 1915-1938, United States expanding birth registration area. U. S. Department of Labor, Children's Bureau. Source, Reports of U. S. Bureau of the Census.

from 1915 to 1934; from 1935 to 1938, the latest year for which data are available, the rate decreased 7 per cent. It is encouraging to note this significant decrease in a short period of time and to know that the mortality rate for 1938 of 13.8 per thousand live births is the lowest ever recorded for the United States birth registration area.

SUMMARY

The importance of the problem of premature birth is shown by the fact that in 1938 there were more than 31,000 neonatal deaths reported by the U. S. Bureau of the Census as directly due to premature birth.

A review of the medical literature prior to 1890 shows that the importance of the criteria for care of premature infants now considered fundamental were recognized in these early years, namely to keep the infant warm, to protect him from infection and to feed him properly.

15. Bundesen, H. N.: Personal communication to the authors.

Progress has been made in the intervening years in developing methods of care in line with more complete understanding of the physiologic handicaps of premature birth.

Breast feeding is generally recognized as important for the welfare of the premature infant but insufficient attention has been paid to the importance of a proper diet for the lactating mother and to the infant, in addition to supplying certain dietary supplements in amounts adequate for his needs.

The care of the premature infant, previously considered only as it concerned the individual infant, has now developed into a community program. Under the provisions of the Social Security Act, title V (administered by the Children's Bureau), the division of maternal and child health of the state health departments of twenty-eight states, the District of Columbia and Hawaii have in progress or have made plans for more or less extensive programs for the care of premature infants, including educational programs, extension of medical and nursing care, and provision of incubators.

The mortality rate from premature birth under one month has shown a decrease of 7 per cent in the past two years. This reflects the improvement in the technic of care of the premature infant and the effect of extension of care to larger numbers of infants through community organization for this specialized service.

ABSTRACT OF DISCUSSION

DR. HARRY LOWENBURG Sr., Philadelphia: When pooled human milk obtained from the maternity ward is employed as the milk supply in feeding premature infants I have noticed every now and then that such infants develop an unusual degree of drowsiness and lethargy about the second or third day. This lethargy and drowsiness disappear when a change is made to some form of bottle feeding. This last fact has made me suspect that the more or less routine administration to mothers of pentobarbital sodium or other such agents may be the responsible factor, especially since I have also had this experience in individual cases when drowsiness in the infant developed and when the mother had received pentobarbital sodium. This is merely surmise which I have discussed with some Philadelphia obstetricians and I have come to no definite conclusion. It is not difficult to agree with the authors in reference to their recommendations to prevent infection, maintain proper body heat and supply sufficient food and fluid. These are not always so easily accomplished, however, as digestive disturbances frequently occur and thwart our efforts. Particularly is this so when insistence is placed on the early administration of concentrated vitamins. It would be profitable if the authors could go a little more into detail and tell us just how they accomplish all the objectives which they mention without disturbing the gastrointestinal tract; in other words, explain their technic.

DR. ETHEL C. DUNHAM, Washington, D. C.: I had hoped that I would not have to answer questions with regard to certain aspects of the care of premature infants about which considerable difference of opinion exists among physicians. Rather, I would emphasize the fact that a great mass of knowledge about such infants is available which is not being used as widely as it should be. Physicians should familiarize themselves with the well established methods of caring for premature infants, so that they can use their specialized knowledge when called on to guide community programs for the care of such infants. One reason for giving this paper is that, with the rapid spread of community programs for the care of premature infants, physicians in local areas all over the United States are being called on for advice with regard to such programs. It is certain that we know much more about the care of premature infants than we did in the past, and that we are putting much of this knowledge into use; but our responsibility is to see that more of this knowledge is given to the physicians who are carrying on these programs.

DIAGNOSTIC PITFALLS OF THE NASOPHARYNX

FREDERICK T. HILL, M.D.

WATERVILLE, MAINE

The Encyclopaedia Britannica defines diagnosis as "the process of identifying the disease by consideration of the history, symptoms, physical signs and examination in every way of the patient." All these factors are important and essential in making a correct diagnosis. In otolaryngology perhaps more reliance is placed on physical signs that are visual than in most other fields of medicine. In the majority of instances the final interpretation of the clinical picture depends on what is seen in the ear, nose, pharynx or larynx. The habit of wearing the head-mirror throughout working hours, so commonplace among otolaryngologists, is an unconscious acknowledgment of the importance of visual examination in this field.

In 1931, in a paper read before this section, I¹ tried to bring out the importance of visual control by direct inspection in performing an adenoidectomy. In a large series of cases in which operations had been previously performed by many different men, a sufficiently high percentage of unsatisfactory results were found to warrant considerable doubt as to the efficacy of many procedures carried out in the nasopharynx. That this ineffectiveness is not limited to the removal of adenoid tissue is obvious. It must be admitted that the diagnosis of nasopharyngeal disease is frequently missed and that many lesions in this region go unrecognized. Carmody, in a recent paper read before the American Academy of Ophthalmology and Otolaryngology, referred to the nasopharynx in the title as "almost unknown in otolaryngology." In searching for an explanation for this too universal error it would seem that the difficulties in easily and satisfactorily visualizing the region might be the answer. Without in any way depreciating the importance of the history and other diagnostic data, the main pitfalls in the diagnosis of nasopharyngeal disease might be considered as due to four causes:

1. Not looking.
2. Not seeing.
3. Not knowing what to look for.
4. Not interpreting correctly what is seen.

The nasopharynx, like the larynx, is not easily accessible to visual examination and, as a consequence, is not always accorded the thorough and complete inspection so essential to a correct diagnosis. Its situation behind the soft palate, out of the direct line of vision, and the occasional difficulties encountered in indirect examination may at times tempt the physician to neglect or to pass rather hurriedly over this phase of the examination. Yet this region is of vital importance in our specialty and often contains the clues to the correct solution of many clinical problems. The excuse "I could not get a good look at the nasopharynx" should never be permitted. No examination should ever be considered sufficient without a thorough inspection of this region.

From the Thayer Hospital.

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

1. Hill, F. T.: Observations Following Adenoidectomy, Arch. Otolaryng. 14: 775-783 (Dec.) 1931.

This, of course, presupposes a routine examination with the postnasal mirror. Sometimes this is neither easy nor satisfactory. The patient may be uncooperative or possess a sensitive, gaggy throat, making it extremely difficult to obtain a satisfactory view of the entire vault. These difficulties usually may be overcome with patience and perseverance, together with a gentle technic and sometimes the use of a small amount of some local anesthetic sprayed in the throat. The postnasal mirror, however, has certain very definite limitations. There is often considerable variation in the contour of the nasopharynx. The anterior tubercle of the atlas may project forward like the prow of a ship with the lateral spaces flaring out behind, or there may be a concavity in the midline of the vault at the superior-posterior angle. It may be quite impossible to inspect these spaces thoroughly by means of the mirror. In addition there is necessarily more or less distortion of the image in any mirror held at a right angle to the object being examined, and this distortion may be further increased by the presence of mucus in the nasopharynx. Sole reliance should never be placed on the postnasal mirror unless the examination is thoroughly satisfactory and the appearance definite beyond all doubt.

The development of direct laryngoscopy, by means of the laryngeal speculum, marked a great advance in our conception of diseases of the larynx. Rarely today would one depend entirely on what is seen with the laryngeal mirror. Similarly in the nasopharynx some direct method of inspection should be employed in every doubtful case in which there is any question of any abnormal condition. I use the nasopharyngoscope almost as a routine, and it is surprising how often small but significant abnormalities can be noted which were not seen with the mirror. Unless prevented by marked septal deviation, the nasopharyngoscope should be passed through both sides of the nose so that the blind area directly ahead of the instrument can be included. In certain cases the pharyngoscope used through the mouth may be useful.

In the final analysis nothing is quite as satisfactory as direct inspection by elevation of the soft palate. Every otolaryngologist is familiar with the difference

Fig. 1.—Schematic drawing of projection of image seen in the post-nasal mirror. Distortion of posterior pharyngeal wall, which is viewed as if looking down a cylinder.

between the appearance of the larynx when seen with the mirror and when viewed through the direct laryngoscope. The same holds true in the nasopharynx and it is much simpler to do.

For years palpation has been an accepted method of examination of the nasopharynx. It is uncomfortable for the patient and is necessarily done so hurriedly that it is usually unsatisfactory to the examiner. Aside from determining the presence of adenoids or ascertaining the firmness of a tumor mass, it gives comparatively little information. I feel that in examining for adenoids, when the child is too young for the use of the mirror or the nasopharyngoscope, it is distinctly preferable to have the patient firmly wrapped in a blanket and to elevate the soft palate with a retractor.

It does not disturb the child any more and gives the examiner more accurate information.

Some years ago Beck advocated retracting the soft palate by means of a rubber catheter passed through the nose. This is often very helpful in operative work but is hardly necessary for the purpose of examination. Yankauer devised a speculum which allows a very satisfactory inspection of the nasopharynx. Often a simple palate retractor will suffice. Usually a minimum amount of local anesthesia in the adult, to control gagging, is advisable. By this direct inspection, using either the speculum or a retractor, one can see the actual picture without distortion and can better interpret the conditions seen with the nasopharyngoscope or the mirror.

Fig. 2.—Direct view of cyst of pharyngeal bursa.

The roentgenogram may be a most useful and important adjunct to visual examination and should be employed in all cases of suspected malignancy. As pointed out by Furstenberg,² the presenting lesion in the nasopharynx may be so small as sometimes to escape detection, or it may be located in the eustachian tube itself; yet there may be considerable involvement of the base of the skull, which can be discovered by x-ray examination.

As common a pitfall as not accurately seeing the nasopharynx is not knowing what to look for. Too often the clinician is satisfied if he determines the presence or absence of adenoids. Hypertrophy of the posterior tips of the inferior turbinate or adhesions across the fossa of Rosenmüller or the eustachian orifice may explain the symptoms of a conduction deafness. Postnasal discharge may indicate a chronic posterior sinusitis. Choanal polypi or the more serious nasopharyngeal fibromas may result in marked nasal obstruction. New,³ Furstenberg,² Hansel,⁴ Heine⁵ and others have called attention to the incidence of benign and malignant tumors in the nasopharynx. Furstenberg⁶ has described tumors developing from the remnants of the hypophysial duct, which he classified as craniopharyngiomas. Ridpath⁷ has reported chordomas arising from the fetal notochord. Yankauer⁸ Dorrance,⁹ Kully,¹⁰ Woodward¹¹ and Eagle¹² have

reported numerous cases of nasopharyngeal cysts or bursae. Beck¹³ refers to primary tuberculosis in this region. Congenital defects, such as atresia of the posterior choanae, are occasionally encountered. Suppuration of the petrous apex may point in the nasopharynx. If one keeps these possibilities in mind the

Fig. 3.—Section of lympho-epithelioma of nasopharynx; reduced from a photomicrograph with a magnification of 280 diameters.

pitfall of incorrect interpretation need not loom so large. Utilization of all other diagnostic data should solve the problem in the majority of cases.

Malignant tumors of the nasopharynx often manifest themselves first by what Hansel⁴ refers to as extra-nasopharyngeal signs and symptoms, usually through involvement of the cranial nerves. New,³ with his vast experience in these cases, has emphasized the diagnostic importance of diplopia, facial pain and disturbances in swallowing as early symptoms. While any of the cranial nerves may be affected, those most commonly involved are the sixth, fifth, ninth, tenth, eleventh and twelfth. Furstenberg² states that the presence of posterior cervical adenopathy, pain referred to the throat or ear and signs of a unilateral conduction deafness should excite the suspicion of a malignant growth of the nasopharynx. Involvement of the pterygoid muscles may result in trismus. Any patient with an unexplained cranial nerve involvement, with or without cervical adenopathy, should be most thoroughly investigated with the thought in mind of a possible malignant neoplasm of the nasopharynx.

A youth aged 17 was seen because of unilateral deafness. He had been under treatment elsewhere and had many inflations and a submucous resection of the septum performed. The posterior cervical nodes were palpable and he had some degree of trismus. Nasopharyngoscopy showed a mass of what appeared like adenoid tissue in the left fossa of Rosenmüller, impinging on the orifice of the eustachian tube. Histopathologic examination showed this to be a "lympho-epithelioma." While he did remarkably well for about two years under high voltage roentgen therapy, he subsequently died from extensive metastases.

A boy aged 14 years was seen in consultation because of marked cervical adenopathy. There was a history of repeated

severe epistaxis necessitating packing of his nose during the preceding few months. Although the source of the bleeding was obviously in the nasopharynx, no consideration had been given to the possibility of a malignant growth. Biopsy showed the lesion to be an epidermoid carcinoma grade 3 and the patient was referred for high voltage roentgen therapy.

Yankauer's⁸ report of 155 cases of nasopharyngeal abscess in 1929 revived interest in so-called Thornwaldt's disease. While not in entire agreement with Yankauer that these were retention abscesses in the recessus medius of a residual adenoid, a number of observers have reported sufficiently large series of cases to suggest that the presence of cysts in the nasopharynx is frequently overlooked. As stated by Kully,¹⁰ there are probably two types: the retention cyst in a residual adenoid, such as described by Yankauer and which is easily opened with a probe, and the cyst, considered by Dorrance⁹ as due to the persistence of an embryonal bursa, originating from adhesions of the notochord to pharyngeal ectoderm. The latter, when viewed by direct inspection, appears smooth, round, yellow or white and from 1 to 2 cm. in diameter. It may have a small opening in its center either exuding secretion or covered with a scab, or it may appear tense and fluctuant. A cutting instrument is required to open this. It contains thick gelatinous material which often shows a positive culture from streptococcus or staphylococcus. Its walls are smooth and shiny. Either type of these cysts may give rise to a postnasal discharge, cause a variety of symptoms affecting the ear or act as a focus of infection. As previously stated, they are frequently overlooked and are best diagnosed by direct inspection of the nasopharynx.

A woman aged 40 was referred by an ophthalmologist because of a persistent cyclitis. Her general physical examination was

Fig. 4.—Section of epidermoid carcinoma of nasopharynx; reduced from a photomicrograph with a magnification of 350 diameters.

negative. Her tonsils had been removed. X-ray examination of the sinuses gave normal results. Examination of the nasopharynx showed a small cryptic bit of tissue directly behind the vomer, covered with a small scab. Marked improvement followed removal. This was a retention cyst in a small residual adenoid.

A man aged 27 complained of postnasal discharge, tinnitus and a feeling of stuffiness in the ears. His tonsils had been

13. Beck, J. C.: *Applied Pathology in Diseases of Nose, Throat and Ear*, St. Louis, C. V. Mosby Company, 1923, p. 170.

removed. His condition had been diagnosed as sinusitis and an antrum operation had been advised. X-ray examination of the sinuses gave normal results. Examination of the nasopharynx showed a round, symmetrical, pale tumor in the midline, somewhat tense and fluctuant, with a small opening in the lower portion. This was operated on under local anesthesia and the lining was destroyed by electrocoagulation. Following this his symptoms gradually subsided. This was a cyst of the pharyngeal bursa.

Such cases as these are far too common for one to view with any degree of complacency the frequency with which the diagnosis of nasopharyngeal disease is missed. While at times the correct diagnosis may present difficulties, the stage at which many of these cases are seen warrants the opinion that the greatest difficulty is due to hasty and incomplete examination and that greater care in this regard would eliminate many of these errors.

CONCLUSION

1. Most of the errors of diagnosis of nasopharyngeal disease are due to the otolaryngologist not accurately visualizing the nasopharynx and not keeping in mind the disease possibilities in this region.

2. Direct inspection of the nasopharynx by elevation of the soft palate is the most accurate and valuable method of examination of this region.

Professional Building.

FIBROMAS OF THE NASOPHARYNX

FREDERICK A. FIGI, M.D.

ROCHESTER, MINN.

Juvenile basal fibromas of the nasopharynx comprise one of the most interesting groups of neoplasms encountered in the upper part of the respiratory tract. Their definite predilection for age and sex and their limited and comparatively inaccessible site of origin, extreme vascularity, tendency toward spontaneous regression and benign histologic structure, yet potential seriousness, render them unique among tumors of the nose and throat.

From Jan. 1, 1910, to Jan. 1, 1940, sixty-three patients having fibromas of the nasopharynx have been examined at the Mayo Clinic. In 1924 New and I¹ reported thirty-two of these cases seen between 1910 and 1923 inclusive. Thirty-one additional patients who had this condition have been encountered since 1923. The entire group of sixty-three cases includes only patients who had fibromas of the juvenile basal type. The group excludes choanal polyps, periosteal fibromas, fibrosarcomas and other forms of fibrous tumors.

Juvenile basal fibromas of the nasopharynx are rare; few reports in the literature present more than a half dozen cases seen by a single individual. A notable exception is the series of fifty-eight "nasopharyngeal fibromas" reported by Shaheen² in 1930. However, Shaheen said that he had encountered these tumors among boys 2, 4 and 7 years of age, also among men aged 48, 60 and 70 years. He noted also that he had not encountered spontaneous involution and disappear-

ance of the neoplasm after the patient had reached the age of 25 years and that he had observed carcinomatous changes in these tumors. Such statements cast considerable doubt on the probability of all his cases belonging to this classification.

The tumors under consideration occur predominantly among male patients. Data concerning some of the patients encountered prior to 1919 are incomplete and because of this only forty-five cases seen since that date are reviewed in detail here.

The tumors present a definite life cycle and a characteristic clinical appearance. They arise most commonly in the vault or high on the posterior wall of the nasopharynx from the periosteum covering the basilar process of the occipital bone and the body of the sphenoid bone but they may spring from the anterior aspect of the upper two cervical vertebrae, the internal pterygoid plate, the region of the foramen lacerum and the pterygomaxillary fossa. The mucoperiosteum lining the sphenoid sinus is also said to be a possible site of origin for the condition. Certain it is that this sinus frequently is found to be involved by neoplasm early in the course of the disease. These fibromas appear at about the age of puberty or slightly earlier than this and continue to be active until the age of approximately 20 to 25 years, at which time they tend to regress spontaneously and in some instances disappear completely.

Fibromas of the nasopharynx usually appear as hard, often almost cartilaginous, rounded, slightly nodular or lobulated, deep red, purplish or grayish tumors occupying the upper portion of the nasopharynx and often extending into one or both nasal fossae as well. Their attachment is most frequently broad, sessile and firm, so that the mass is almost immovable. At times, and especially in the case of tumors of slow growth and long duration, there is a definite pedicle, and a freely movable mass can be seen below the palatal border. Multiple secondary attachments to the pharyngeal or nasal wall may be present following unsuccessful attempts at operative removal. The intranasal prolongations of the tumor may crowd the septum against the lateral wall and they may present in the anterior naris or even protrude from the nostril. Other extensions may invade the retramaxillary fossa, antrum, orbit, ethmoid sinuses, and the sphenoid sinus and even the cranial cavity. These prolongations are said to grow most intensively where they encounter the greatest obstacles. In several of our cases a tumor arising in the nasopharynx or pterygoid fossa was bulging the cheek lateral to the tuberosity. The tumor is covered with normal mucous membrane, and tortuous vessels often stand out prominently on the surfaces. This in itself is frequently a very striking clinical feature. Ulceration is not often seen except as a result of trauma or previous therapy.

The extent of these tumors varies greatly. Although they usually spring from some point of origin situated high on the posterior wall or the vault of the nasopharynx, in our experience comparatively few of them are limited to this cavity at the time the patient reports for examination. The inherent activity of the growth, together with the stimulation induced by repeated incomplete treatment previously carried out in the majority of these cases, unquestionably were factors in such extension beyond the aforementioned cavity. The nasopharynx was involved in all forty-five cases in this series which were studied in detail, but in only eleven

cases were the tumors confined to this region alone. Both nasal fossae were involved in three cases, the left alone in eighteen instances and the right in thirteen.

Pressure of the expanding neoplasm often results in a remarkable degree of destruction of the bone with

Fig. 1.—Schematic representation of fibroma of the nasopharynx and nasal fossa, with sessile attachment in the vault of the nasopharynx. The pressure of the tumor mass has destroyed a considerable portion of the basilar process of the occipital bone and of the body of the sphenoid bone.

which it comes in contact. This osseous loss appears to be the result of pressure absorption. As a result of it the tumor is able to pass readily through narrow fissures such as the lacerated foramen and even to extend directly through the base of the cranial cavity. A fatal termination at times occurs as a result of this extension. This type of destruction of bone is seen not infrequently in association with other neoplasms situated elsewhere about the head. In fact, any slow-growing encapsulated mass of soft tissue developing in contact with a bony surface is likely to produce a cavity in the bone and may actually perforate it. This phenomenon often occurs in connection with mixed tumors of the hard palate and with dermoid cysts adjacent to the orbit (fig. 1).

In the series under consideration, symptoms had been present for from one month to six years at the time of examination of the patients in the clinic. Nasal obstruction was the first symptom noted by most of the patients, although epistaxis had occurred primarily in a few instances. The female patients ranged in age from 10 to 22 years and the appearance of symptoms dated from the ages of 7 to 16 years, having been present for from one and a half to six years and averaging four years for the series. The male patients were from 10 to 30 years of age. Symptoms among the male patients had first appeared at the age of 10

to 23 years and had been present for from one month to six years, averaging a little more than one and a half years in duration. Pain was not a prominent feature in any of the cases. Marked difference in the rate of growth of the tumor was noted in different cases. Some of them, especially among younger individuals, were growing so rapidly that they appeared clinically to be malignant. The tendency toward complete spontaneous regression following partial excision mentioned by Ewing,³ who stated that this tendency also has been observed by Bensch, Grünwald, König, Bruns and Zarniko, was not encountered among the patients in this group.

Roentgenographic studies, particularly of the nasal accessory sinuses in these cases, often will furnish considerable information additional to that obtainable on physical examination alone and should be made whenever the indication presents. The tumor in the nasopharynx will as a rule be revealed best in lateral roentgenograms taken to show the upper part of the cervical region of the spinal column or the larynx. Pathologic processes are commonly present in the accessory sinuses in these cases and may be referable to direct invasion of the cavity by the neoplasm or to secondary inflammatory changes resulting from nasal obstruction and interference with drainage and ventilation (fig. 2).

Roentgenograms of the sinuses were made in forty of the forty-five cases in which detailed study was carried out. Results of these roentgenograms were negative in seven instances; the remaining thirty-three showed evidence of pathologic processes in the sinuses, nose, nasopharynx or orbit. The pathologic changes included the presence of a tumor mass in one or more of the sinuses or in the adjacent structures, diffuse

dulness of a single sinus, pansinusitis and, in a few instances, only thickened membrane. The sphenoid sinus was found to be involved in eight cases, the increased density being interpreted as a direct extension of the neoplasm in the vault of the nasopharynx. This observation always increased the hazard of treat-

ment, which was invariably more protracted in these cases. The right antrum showed pathologic changes in twelve instances, the left in eighteen, although the antrums actually were invaded by the neoplasm in only seven cases. The ethmoid sinus presented roentgeno-

graphic evidence of involvement by the tumor in five cases and the basisphenoid bone, sella and orbit in one (fig. 3).

These tumors are primarily pure fibromas and microscopically consist of dense connective tissue. They are extremely vascular and the vessels are often cavernous in type. In addition, more or less inflammatory reaction is usually present, so that different portions of the tumor may contain inflammatory tissue, fibromyxoma or fibro-angioma. Friedberg⁴ has recently suggested that these tumors be designated "vascular fibroma" or "angiofibroma" because of their histologic structure. The lack of muscle fibers in the walls of many of the large vessels and the fact that they are enclosed in dense fibrous tissue explain the profuse and persistent bleeding encountered in these cases. Cellular portions commonly are present in the tumors and often lead to a mistaken diagnosis of fibrosarcoma. Although deposits of calcium, cartilage and bone were said by Ewing to be rare, they have been reported in a number of instances. Ringertz⁵ reported a case in which fibroma arose in the sphenoid sinus and in which the extent of the deposits of calcium led to a mistaken diagnosis of osteogenic sarcoma.

Generally speaking, biopsy should be made in all cases of neoplasm occurring about the upper part of the respiratory tract prior to the institution of treatment. Even though the diagnosis appears obvious on clinical

examination, microscopic study may reveal the presence of a pathologic process entirely different from that suspected. Fibromas of the nasopharynx provide one of the few exceptions to this generalization. The laryngologist who has seen a few of these neoplasms can as a rule recognize them rather definitely on gross observation. However, in cases in which the tumor is growing actively, especially when it is recurring following previous treatment and when inflammation is present, the clinical picture often strongly simulates a malignant neoplasm and biopsy may be absolutely necessary for differentiation. The chief objection to removal of tissue for histopathologic study is the profuse bleeding that invariably ensues after such a procedure. At times this bleeding is difficult to control and, if positive recognition is possible without microscopic examination, biopsy should be avoided. In recent years at the clinic we have not taken tissue for microscopic study in many of these cases but have based the diagnosis on the individual history, the hardness of the tumor, the age of the patient and the clinical picture. Malignant change occurring in nasopharyngeal fibromas has been reported by some observers. This has not been definitely proved, however. It seems much more likely that in such cases a fibroma apparently activated by trauma, infection or some other cause was assumed to be a sarcoma, that a mistaken diagnosis of fibroma had been made in a lesion that was primarily malignant or that the histopathologic picture was misinterpreted (fig. 4 *a* and *b*).

Fig. 4.—Fibroma of the nasopharynx: *a*, the tumor from which this section was made occurred in a youth 18 years of age and had produced symptoms for only two months; *b*, the tumor from which this section was made occurred in a boy 16 years of age and had produced symptoms for one and a half years. Note the marked vascularity of both neoplasms.

In the literature many types of tumors appear to have been confused with fibromas of the nasopharynx; among these, myxomatous choanal polyps which had attained considerable size, and also periosteal fibromas, fibrosarcomas and various other types of malignant

neoplasms. Choanal polyps must be carefully distinguished, but they should cause little difficulty in this connection for they arise in the mucous membrane of the nose and accessory sinuses, most often the antrum, and are associated with inflammatory changes in the mucosa. They may, however, present in the nasopharynx as a mass of such size that their site of origin cannot be definitely determined clinically. They are usually lighter in color, much softer and less vascular than true nasopharyngeal fibromas and are freely movable, which is in decided contrast to the majority of juvenile basal fibromas. Moreover, removal of them presents a much less serious problem than does that of pharyngeal fibromas. Periosteal fibromas may be difficult to distinguish in their clinical appearance, but they show no predilection for age or sex as do the juvenile fibromas. They usually appear as firm, grayish red, sessile, nonulcerated immobile tumors within the nose or accessory sinuses, but they may develop externally about the superior maxillae or about the nose. They spring from the periosteum or the mucoperiosteum. They are less vascular than the nasopharyngeal fibromas and their cellular structure is more mature. Although they at times show much formation of new bone they must, as Ringertz pointed out, be distinguished from true osteofibromas, which are not infrequently encountered about the superior maxillae. Intranasally they may develop on the septum or the lateral wall. Chiari⁶ reported a case in which a tumor of this type, arising in the ethmoid sinus, eroded the base of the skull and extended intracranially. This same complication apparently developed in a patient who had been examined in the Mayo Clinic and who received treatment at home. At the clinic we also encountered a tumor of this nature arising on the outer aspect of the nasal bridge in a child 4 months of age. A tumor had been present at birth and had been removed at the age of 1 month. At the time of removal of a recurrence of this neoplasm at the clinic when the patient was 15 months old the tumor measured 1 cm. in diameter. Tumors of this type were observed as being situated intranasally in two male patients aged 50 and 64 years, respectively; also in a woman 23 years of age, in two boys 13 and 19 years of age, respectively, and in several other patients. In the case of the man aged 64 the tumor had arisen within the antrum on the lateral wall, involved the nose, perforated the alveolus in the region of the tuberosity and bulged into the mouth at this point. Histopathologically it was a myxofibroma. No recurrence followed its removal with diathermy. These tumors often completely fill the antrum and by pressure absorption thin out the bony walls to the thickness of paper. In a number of instances they apparently have been reported as true nasopharyngeal fibromas. Some years ago I encountered a firm, dark red, fibrous tumor of the nasopharynx in a woman aged 60 who gave a history of nasal obstruction of two years' duration. The mass measured approximately 3 cm. in diameter and filled a large portion of the nasopharynx. On the basis of its clinical appearance it might well have been considered a true nasopharyngeal fibroma. On removal with electrocoagulation, however, it proved to be merely an extraordinarily large and firm hypertrophic tip of the inferior turbinated process.

Although fibromas of the nasopharynx tend to undergo spontaneous regression after the patient is

from 20 to 25 years old, this tendency cannot be relied on sufficiently to justify delaying therapy in these cases. A fatal termination is an ever present possibility in this condition and active treatment always should be carried out.

The treatment of nasopharyngeal fibromas at the Mayo Clinic has undergone considerable change in the past twenty-five years. Prior to 1915 surgical procedures were resorted to almost exclusively at the clinic as well as elsewhere. Experience generally with such measures was a high mortality rate and frequent recurrence, necessitating repeated operations. Many of the procedures advocated were decidedly mutilating in effect, and uncontrollable hemorrhage was at times encountered. Kobylinski,⁷ in a series of ten cases, reported three deaths caused by hemorrhage. Wojatschek⁸ reported eight cases in which operation was performed by the transpalatal or transmaxillary route. Although he had no operative mortality, several patients had recurrences and one died subsequently of the disease. Experience at the Mayo Clinic with eight cases, in five of which surgical treatment was administered during the period of 1910 to 1915 inclusive, was no more satisfactory than this, which accounted for the change in our method of treatment.

From 1916 to Jan. 1, 1924, twenty-four patients suffering from fibromas of the nasopharynx were examined in the clinic. Twenty-three were treated with radium, the treatment being applied by three methods. In the first or early instances of the condition a T shaped lead applicator with a 50 mg. tube of radium in the trough of the T was held in various positions against the tumor in the nasopharynx. The original dose usually consisted of application of a 50 mg. tube for from ten to fifteen hours. It was difficult to apply the radium accurately in this manner, and severe reaction in the adjacent structures often occurred. In two cases the palate was perforated. Such complications were later prevented by protecting the posterior surface of the palate with a retractor made of 2 mm. of sheet lead covered with a rubber finger cot, and by more accurate dosage.

In the second group of cases steel points containing radon or radium element were inserted directly into the tumor, the number of points and dosage depending on the size of the mass. In the third group emanation seeds or radon points, first of glass and later of gold, were implanted. The value of the seeds ranged from 0.5 to 1 mc., the latter having since been found to be the more satisfactory. The number of points used depended on the extent of the tumor. This type of treatment, as well as the insertion of steel points, is still used in some cases, especially to supplement other therapeutic measures. The radium treatments were repeated at intervals of from two to three months, depending on the reaction observed and the result of previous therapy. Secondary applications usually were somewhat smaller than those used primarily.

Of the forty-five patients who had fibromas of the nasopharynx who were examined at the Mayo Clinic subsequent to the beginning of 1919, three patients did not stay for treatment. For the remainder, radium therapy or electrocoagulation, either alone or combined, was employed. Since the beginning of 1924 we have

7. Kobylinski, quoted by Hellat, P.: Die sogenannten fibrösen Nasenrachenpolypen: Ort und Art ihrer Insertion und ihre Behandlung, *Arch. f. Laryng. u. Rhin.* 25: 329-344, 1911.

6. Chiari, quoted by Ringertz.⁵

used surgical diathermy with increasing frequency in the treatment of these tumors and in most instances it has been supplemented with radium. Of the forty-two patients treated, twenty-two received radium therapy alone, seventeen diathermy combined with radium, two electrocoagulation alone, and one roentgen therapy. The patients treated exclusively with radium received an average of six applications, counting implantation of radon points or steel points or the use of an applicator as separate from radium packs, even though this intranasal or intrapharyngeal therapy was used at the same time as external treatment. Steel points were implanted into the tumor in thirty-four cases and radon seeds in eleven. Radium tubes were applied directly in contact with the tumor in the nasopharynx by means of an applicator in sixteen cases. Radium packs were employed in eight. The one patient for whom roentgen therapy was used was hemophiliac. Among the patients in whom the tumor was treated with electrocoagulation primarily, an average of two applications of radium including the one used at the time of coagulation were given. Almost without exception, implantation of steel points or of radon seeds was used in these cases. The nineteen patients who were treated with electrocoagulation received only one application in twelve instances, two in five and three in two.

The length of time that patients were under treatment varied from two months to six and a half years among those for whom radium and diathermy were employed and from six months to four and a half years for those treated with radium. Two patients in the group in which electrocoagulation was used had unusually large and active tumors that proved to be very resistant to therapy. Both of these patients lived a considerable distance from the clinic and it was impossible for them to return at regular intervals. In addition, the sphenoid sinus was extensively involved in one of the patients and the antrum, cheek, pterygomaxillary fossa and orbit, as well as the nasopharynx and the nasal fossa, in the other. The former of these patients was under treatment for four and a half years, the latter for six and a half years. Following electrocoagulation and implantation of radium on one occasion in this latter patient, septic meningitis developed with loss of consciousness, hemiplegia and a polymorphonuclear cell count in the spinal fluid as high as 1,152. For some time it was thought that a fatal termination was inevitable, but the patient gradually recovered and with one subsequent insertion of radium the tumor entirely disappeared, leaving no residuum. It is questionable whether any other form of therapy would have eradicated the neoplasm in these two patients in a shorter period. With the exception of these two instances, the average length of time the patients receiving diathermy and radium combined were under treatment averaged ten months. Two patients for whom electrocoagulation alone was employed each were cured in four months. The patients receiving radium therapy alone were under treatment an average of 18.6 months. It seems certain, however, that the time required to eradicate these tumors with irradiation might have been shortened materially if the patients had been able to return at regular intervals for treatment. Implanted radium was more effective than radium applied to the surface of the tumor or externally in the form of radium packs.

Electrocoagulation often will entirely eradicate tumors of the type under consideration in a single sitting, a result which is rarely accomplished with radium, but

electrocoagulation does involve a greater hazard than does irradiation. Profuse hemorrhage is frequently encountered when surgical diathermy is being used in these cases and in some instances hemorrhage is so active that it cannot be controlled by the coagulating process, and electrocoagulation cannot progress because of it. In a few such instances in this series it was necessary to discontinue electrocoagulation and to insert a firm pack into the anterior portion of the nares, and also postnasally, to stop the bleeding. In a few of these cases ligation of the external carotid artery was required on removal of the nasal pack a few days later or on separation of the slough at the end of from ten days to two weeks. In two instances treated early in the series perforation of the hard palate developed following the use of diathermy combined with radium. This complication might well have been obviated had an attempt not been made to eradicate these tumors in a single sitting. In fact, the end results in these cases have been equally satisfactory and fewer complications have been encountered when less intensive electrocoagulation and irradiation have been employed primarily and the treatment has been repeated on one or more occasions subsequently. Atrophy of the mucous membrane of the nose and nasopharynx occurs almost invariably following treatment of fibromas in these situations with either radium or surgical diathermy. Such atrophy is always more pronounced after irradiation, however, and the associated foul crusting frequently causes severe periodic hemorrhages later. The crusting and dryness of the mucosa incident to the atrophy can be controlled to a great extent and often entirely eliminated by increasing the patient's intake of fluids, by the daily administration of iodides and by the frequent use of a liquid petrolatum nose and throat spray. Although such atrophy does not result from avulsion or sharp excision of these tumors, the greater hazard of the latter procedures renders them inadvisable in many of these cases. Sancho and Ferrer⁹ in 1929 reported five cases of nasopharyngeal fibroma in which the lesions ranged in size from that of a walnut to that sufficient to fill the nasopharynx and most of one nasal fossa; these tumors were removed by avulsion without mortality. The snare was introduced through the nostril. Although this procedure might have been carried out in a few of our cases, it would not have been feasible in the great majority of them because of the large size, multiple attachments, broad sessile base and extreme vascularity of the tumors. The possibility of engaging the majority of these tumors in a snare is wholly inconceivable; the fact that many of them were recurring following previous treatment unquestionably was an important factor in this. Villoria¹⁰ has recently reported three cases of fibroma of the nasopharynx in which surgical removal was carried out through a Moure transmaxillonasal approach following preliminary laryngotomy. The surgical procedure was supplemented with irradiation.

In using surgical diathermy for fibromas of the nasopharynx and nasal fossae, the electrode usually is inserted through both the nostril and the mouth. A vulcanite nasal speculum is used when approach is made through the nose, in order to avoid injury to the nostril. For coagulation of that portion of the

9. Sancho, R. V., and Ferrer, E. A.: Estudio anatómico, clínico y terapéutico de los fibromas nasofaríngeos, *An. d. Hosp. de l. Santa Cruz y San Pablo* 3: 235-264 (Sept. 15) 1929.

10. Villoria, L. L.: Fibromas naso-faríngeos (fibromas sangrantes de la pubertad masculina), *Tipografía Americana*, 1940.

tumor which is situated in the nasopharynx, the soft palate is retracted by means of a rubber catheter introduced through one nostril and brought out through the mouth. Additional protection to the soft palate is afforded by means of a flat piece of vulcanite or some other nonconductor threaded over one of these catheters and drawn back up between the posterior surface of the soft palate and the tumor. The electrode which is introduced through the mouth is insulated, except for a few millimeters at its tip, with a coat of duco cement or it is covered with a rubber catheter. The distal 2 or 2.5 cm. of this electrode is bent upward at a right angle to permit contact with the tumor (fig. 5). During the actual coagulation the point of the electrode and the tumor in the nasopharynx are observed by means of a nasopharyngeal mirror and an insulated suction tip is held adjacent to the region of electrocoagulation to remove blood, mucus and steam, to prevent excessive scalding of the normal tissue and to keep the mirror from fogging too rapidly. Intra-

Fig. 5.—Technic of electrocoagulation of a nasopharyngeal fibroma: A rubber catheter introduced through the nostril and brought out through the mouth retracts the palate, thereby rendering the tumor more accessible, while a vulcanite disk threaded over the catheter protects the nasal surface of the palate. A suction tube is held adjacent to the point of the insulated electrode during electrocoagulation.

tracheal anesthesia usually is employed, the tracheal tube being introduced through the mouth. This permits of placing a gauze pack firmly in the hypopharynx so that the possibility of blood gravitating into the larynx and trachea is obviated. The portion of the tracheal tube which is situated in the pharynx tends partially to obstruct the surgeon's view of the nasopharynx, but this type of anesthesia is much safer in these cases than colonic or intravenous anesthesia. In the few instances in which it was impossible to make progress with electrocoagulation because of extreme vascularity, surgical diathermy was discontinued and radium points were inserted into the tumor.

The results of treatment of fibromas of the nasopharynx at the Mayo Clinic with radium and electrocoagulation either alone or combined have been very gratifying. There has been no mortality in these cases to date and all the patients who have received the therapy either have been cured or are well on their way to complete recovery. One patient, a boy, who

came in three years prior to the time of this writing at the age of 13 years suffering from an extensive fibroma which involved the retromaxillary fossa, right side of the nose, nasopharynx, sphenoid sinus and orbit and which bulged the cheek, still presents increased density in roentgenograms of the sphenoid region. There is no clinical evidence of the neoplasm aside from this roentgenologic density, and the patient has no symptoms. Two patients in whom such tumors had almost disappeared at the time they were last observed nine and a half and thirteen years prior to the time of writing, respectively, have not been heard from since. It would seem likely that these patients have recovered. One patient for whom diathermy and radium were used on two occasions began to suffer from a recurrence fifteen months after the last treatment. Because of the great distance from the clinic at which this patient lived, he was unable to return but when last heard from apparently was progressing satisfactorily under radium therapy at home. Another patient who had received a single radium treatment wrote that a portion of the tumor was still present in the nasopharynx, but he did not mention symptoms associated with this condition. These results contrast strikingly with the experience of most laryngologists in dealing with tumors of this type by surgical measures.

It is interesting to note the age of these patients at the time of complete disappearance of their nasopharyngeal fibromas. Actually this point is the crux in determining the efficacy of therapeutic measures in these cases, since the tumors tend to undergo spontaneous regression after the patient reaches the age of approximately 25 years. Five of the patients had attained the age of from 20 to 24 years at the time treatment with radium was commenced, whereas eight in this group of twenty-two patients treated in this manner were 20 years or more of age at the time of complete disappearance of the tumor. Only one patient of the twenty-two was more than 25 years of age when cured; this patient was 24 years old at the time treatment was started and 26 years when cured. Among nineteen patients treated with electrocoagulation and radium, three were from 21 to 25 years of age at the time this procedure was initiated. Five patients (26 per cent) in the group had attained the age of 20 to 25 years at the time of complete disappearance of the tumor; 73 per cent were less than 20 years of age; 63 per cent of those treated exclusively with radium were less than 20 years of age when cured.

Although these tumors are benign, the improvement in the patient's general health that commonly follows eradication of the mass is often as striking as that noted after removal of a large infected malignant neoplasm. A gain in weight of from 15 to 20 pounds (7 to 9 Kg.) within the course of a few months is not unusual. One girl in this series, 14 years of age, gained 35 pounds (16 Kg.) in four months. Frequently a similar period of time will result in the patient's being transformed from an asthenic, pale, anemic individual into a robust person of normal vigor and vitality. The change of course occurs more promptly if the tumor is eradicated with a minimal loss of blood, but it has been seen in cases in which severe hemorrhage occurred postoperatively. It is accounted for by control of the frequent hemorrhages to which the patients have been subject, clearing the foul, fetid nasal discharge and recession of the associated inflammatory process and restoration of the nasal airway and of the patient's appetite.

SUMMARY AND CONCLUSIONS

Sixty-three cases of juvenile basal fibroma of the nasopharynx observed at the Mayo Clinic were studied. Fifty-eight of the tumors occurred in male patients; five were present in female patients. The patients ranged in age from 10 to 31 years at the time of examination. The nasopharynx was involved in all the forty-five cases studied in detail, the nasal fossae in thirty-four. The antrum, sphenoid and other accessory sinuses were invaded in a number of instances. Removal of tissue from these tumors is always attended by profuse bleeding and in some of the more recent instances of the condition biopsy was not performed, the diagnosis being based on the history, the age of the patient, the hardness of the tumor and the characteristic clinical picture. Surgical removal of these tumors involves considerable risk, and recurrences are frequent. Implants of radium and electrocoagulation supplemented with radium are the most effective forms of treatment in these cases. By means of electrocoagulation and insertion of radium a tumor of this type can at times be eradicated with a single application, but fewer complications are likely to be encountered if treatment is carried out in stages. There was no mortality in the series. All the patients who received complete therapy are now well except for a boy, 16 years of age, who is still under treatment at the time of writing.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. FIGI AND HILL

DR. JOSEPH D. KELLY, New York: Examination of the nasopharynx is not easy at the best; however, it must be done in all questionable cases. I do not believe there is any one method of examination which can be considered complete. Dr. Hill seems to think that we have overlooked the possibilities of the Yankauer boot. The use of the Yankauer boot is not easy and the field of vision is limited. It is necessary to anesthetize the pharynx and nasopharynx, and even then, in sensitive patients, retching is not obviated. The Yankauer is an excellent instrument for the examination of localized areas, such as the fossa of Rosenmüller and the posterosuperior lateral pharyngeal wall. The palate retractor alone gives a fair view of the lower half of the posterior nasopharynx, and this instrument, with a good sized nasopharyngeal mirror, is an excellent procedure. But let us not lose sight of the nasopharyngoscope. I think one should have two sizes to accommodate the large or the small nose or the noses of patients having nasal obstruction. The use of the nasopharyngoscope is simple and gives a fund of information with the least discomfort to the patient. Also one may treat the nasopharynx with the aid of the nasopharyngoscope more readily than by any other method. Aside from the methods of examination, the most important thing is the knowledge and experience of the examiner. If the examiner does not recognize the normal he will not appreciate the abnormal, and the examination is useless. I think that we will all agree that we do not have to fear the specialist who says "I don't know," but we must give a wide berth to the fellow who thinks he knows and does not know. Dr. Figi is to be congratulated on giving us a most complete paper and the data on one of the largest, if not the largest, series of nasofibromas of the nasopharynx, and he has brought out very definitely the characteristics of these tumors, such as the fact that they predominate in male patients—twelve males to one female. The main impression that Dr. Figi leaves is that the surgical treatment of nasofibromas is something of the past and that the safest way and surest way of effecting a cure is a combination of radium and electrocoagulation.

DR. CHARLES J. IMPERATORI, New York: Among the methods stated by Dr. Hill, he included that of palpation of the nasopharynx. Definitely, that is a most important method but most of the time we use our nail and not the ball of the finger. Just

recall how you examine the nasopharynx. The index finger is placed in the nasopharynx with the ball of the finger anteriorly and the nail in contact with the pharyngeal wall. Instead, turn your finger around and apply the ball of the finger. The Hassinger or modification of a White palate retractor, I have found, is an extraordinarily good instrument in the examination of the nasopharynx but the Coakley tonsil probe will give almost as much information. The use of a Frankel tongue depressor and a tilting mirror, a No. 2 or No. 3, will give a great degree of information. Most patients can be examined by this method, possibly 60 per cent. With the other 40 per cent, one must use the nasopharyngoscope. There are many men who never use the tilting mirror or postnasal mirror but depend entirely on the use of the nasopharyngoscope. The use of the Hayes pharyngoscope or the modification of the Hayes-Beck instrument introduced into the mouth gives one a great degree of information in the nasopharynx. Then there is the method that I have designated as anteroposterior rhinoscopy, which consists of looking through the nose, into the pharynx, after having shrunk the tissues. That should be a routine practice in the examination by all otolaryngologists, especially at the first examination. This procedure is attained only by understanding how to focus the head mirror. The cone of light must be focused on the pharyngeal mucosa. One assists oneself somewhat by having the patient say "H," in other words raise the soft palate, and frequently one can see a light reflex, depending, of course, entirely on the amount of shrinkage that has occurred. I use a shrinking solution containing 1 per cent cocaine and 1:5,000 epinephrine. The use of lateral roentgenograms and this new method of laminography I think is going to help a great deal in outlining tumors in the nasopharynx. To discuss Dr. Figi's paper is almost like bringing coals to Newcastle. A report of forty-five case histories represents a very large experience in this particular condition. Definitely he has pointed out that there are two methods of arriving at the diagnosis: the clinical history and the physical examination. The clinical history usually is as follows: a male at puberty, disturbance of the hearing and nasal obstruction, disturbance of nutrition, loss of appetite, spontaneous epistaxis and frequently the appearance of considerable loss of mentality because of the interference with breathing and the blocking of the posterior choana. In the method of arriving at the diagnosis, the new growth is determined by physical means entirely and not by biopsy.

DR. GORDON B. NEW, Rochester, Minn.: Dr. Hill has done an excellent job in calling to our attention the necessity of a careful examination of the nasopharynx. Of all the lesions seen in this region, the malignant ones seem to be of most importance from a diagnostic standpoint. Eighteen years ago before this section I reported seventy-nine cases of malignant tumors of the nasopharynx examined in the previous six years, bringing out the fact that the symptoms these tumors present are not generally known and that the percentage of these tumors which produce symptoms referable to the nose and throat is comparatively small. Since then, from 1922 to 1936 inclusive, we have seen at the Mayo Clinic approximately 500 malignant tumors of the nasopharynx and during this period have been further impressed with the necessity for a careful examination in this region and the fact that many indeterminate diagnoses are cleared up by the finding of a malignant tumor. Of the seventy-nine cases reported in 1922 there were twenty-one presenting symptoms referable to the eye, twenty-nine referable to the ear, thirty-eight referable to the nose and pharynx, fifty-one referable to the glands of the neck, four referable to involvement of the gasserian ganglion, two referable to involvement of the jugular foramen and the nerves that pass through it, and eleven symptoms referable to intracranial involvement. Patients with malignant lesions of the nasopharynx frequently consult the ophthalmologist on account of external rectus palsy or ptosis, the neurologist on account of pain in the fifth nerve or the symptoms of intracranial involvement, the otologist on account of pain in the ear or discharge, the medical consultant regarding the presence of a gland in the neck of an indeterminate origin, or the dentist on account of the possibility of a wisdom tooth being a factor in the pain. It is possible in patients with pain in the face and ear or involvement of one or many of the cranial nerves to clear up an indeterminate diagnosis by finding a small

epithelioma of the nasopharynx. The results of treatment in these cases are much better than is generally thought. Radiation used externally and directly into the nasopharynx is the best method of treatment, and some patients are alive and well five and ten years following treatment. Dr. Figi has reported results of treatment of sixty-three patients with fibromas of the nasopharynx. As he has outlined, the use of surgical diathermy and radium gets these patients well with the least risk. In the treatment of most tumors it is essential that the tumor be entirely removed at one time. In the treatment of this particular type of tumor, that is a fibroma, the best results are obtained with the least risk by removing them in stages.

DR. E. P. FOWLER JR., New York: I didn't intend to discuss this paper, but since Dr. Kelly gave me credit for some one else's case I thought I ought to straighten the matter out. The case described was Dr. Morris Heller's. He was responsible for the successful diagnosis; I merely observed the case. I should like to ask Dr. Figi whether he uses only inhalation anesthesia for these cases, whether he is afraid of explosions from his diathermy and whether he ever uses intravenous anesthesia. I should like to leave two thoughts that were given to us by Dr. Coakley when he was discussing nasopharyngeal pathology with his interns. Dr. Coakley suggested that a probe be placed in the nose and the distance to the nasopharynx measured. If it is deeper on one side than the other, or something can be pushed around, one can be pretty sure of a tumor. Another dictum was "Always do a biopsy on a unilateral adenoid."

DR. FREDERICK T. HILL, Waterville, Maine: I will agree, of course, with Dr. Kelly. I tried to bring it out in the paper that all methods of examination should be used to arrive at a diagnosis; that one method would help the other in visualizing the region. It is so difficult to get a complete view of the nasopharynx that every method which will bring into view any part of the nasopharynx should be utilized, forming something of a composite picture. I am glad he mentioned the two sizes of nasopharyngoscopes. They are very useful. With any tumor in the neck one should keep in mind the possibility of a malignant nasopharyngeal growth. It is somewhat unfortunate that, at least with these Schmincke tumors in the nasopharynx, we may get what seems for a time to be satisfactory results but most of them go bad in about two years. Dr. Imperatori mentioned palpation. In my paper, which I didn't have time to read in full, I referred to palpation as a method of diagnosis. While we use it, it tells us comparatively little beyond the firmness of the tumor mass. I feel that it is advisable in examining a young infant for the presence of adenoids to retract the soft palate. It gives us more information. There is one thing about the shrinking of the nose for anterior examination. Cocaine and epinephrine are used in a rather routine manner, but once in a while we have a patient who has quite an idiosyncrasy to epinephrine and it may prove quite unpleasant. After it was used on my own nose, and I sneezed steadily for days, I discontinued using epinephrine. I think it is a great privilege to have Dr. New come into this discussion with his experience of 500 cases of tumor of the pharynx.

DR. FREDERICK A. FIGI, Rochester, Minn.: The discussers have been very generous. Answering Dr. Kelly's question concerning the opportune time for using radium in these cases, we usually insert radium needles or gold radon points immediately following the electrocoagulation, although they may be employed at any time either preceding or following the operation. As a rule it is necessary to use radium on one or more occasions following the initial application. Concerning the anesthesia that Dr. Fowler inquires about, intratracheal, ether, nitrous oxide and carbon dioxide are usually employed. The patient is anesthetized primarily with nitrous oxide and ether and is carried largely with a combination of nitrous oxide and carbon dioxide. During actual electrocoagulation the ether must, of course, be discontinued. There is apparently little danger of an explosion if the ether is discontinued, the gauze pack in the hypopharynx changed, the patient permitted to take a few deep breaths and the gas machine flushed with carbon dioxide before electrocoagulation is proceeded with. Intravenous sodium pentothal has been employed in a few instances.

CUTANEOUS MANIFESTATION FROM TOBACCO

WITH SPECIAL REFERENCE TO ARSENICAL
EXFOLIATIVE DERMATITIS

E. E. BARKSDALE, M.D.
DANVILLE, VA.

My purpose in this paper is to call attention to another possible source of arsenic poisoning, namely tobacco. All of the tobacco on the American market contains arsenic in a form which may be taken up by the human body.

For years farmers have been using lead arsenate as an insecticide on tobacco to kill the horn worm. Nothing is done during the agricultural or manufacturing process to remove it. Probably nothing can be done.

Usually when any worker attempts to tie up a manufacturing process in which large amounts of money are involved with human diseases, a great furor is raised. This is not my intention.

Lead arsenate is essential to the tobacco industry. It should be considered as an industrial hazard. Farmers use it as an insecticide because it is the most efficient and inexpensive one available. Indeed, its efficiency is probably responsible for the fact that it remains on the tobacco when it reaches the consumer. It has the property of sticking to the tobacco. This is the reason why it is so effective. Remaining on it throughout, it kills the young worms as they are hatched. It is impossible to wash it off because in so doing the tobacco would be ruined. There is no chemical process known that will remove it.

For the past several years the United States Department of Agriculture has not recommended lead arsenate as an insecticide. Instead it recommends a preparation called cryolite. Farmers will not use this, first, because it is a little more expensive and, second, because it is much more difficult to use. It has to be applied to each individual plant. On the other hand, lead arsenate is effective in the hands of inexperienced labor. In fact, if it is thrown up in the air and blown across the field it will do just as well.

Remington¹ in 1927 reported that tobacco contained arsenic. He also stated that "the habitual user of tobacco is in daily contact with appreciable amounts of arsenic" and concluded that "the possibility of chronic arsenic poisoning from the use of tobacco is not to be dismissed without more evidence." Gross and Nelson,² of the United States Department of Agriculture, reported in 1934 that tobacco smoke contained arsenic. Drs. C. N. Myers and Binford Throne concluded from their work that arsenic was a factor of great importance in about 30 per cent of cases of eczema. They attributed the arsenic to the increased use of arsenate spray for the destruction of insects.

Consumers Research in 1938 analyzed five brands of cigarets and reported the arsenic content to be too high for safety to the heavy smoker.

The United States Pure Food Laws allow only 1.43 parts per million for arsenic. Zeidler and Wagner

Miss Louise Jakeman, Miss Margaret Tatum and Dr. C. W. Purcell, of Danville, Va., gave valuable aid and suggestions in this experiment.
Read before the Section on Dermatology and Syphilology at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.
1. Remington, R. E.: J. Am. Chem. Soc. 49: 1410, 1927.
2. Gross, C. R., and Nelson, O. A.: Am. J. Pub. Health 24: 36 (Jan.) 1934.

reported in 1937 that the arsenic content of tobacco was fifty times that allowed in foods.

It is only fair to note that no user of tobacco could possibly consume all the arsenic present. The spray is frequently used on vegetables and fruits, but they are usually washed before eating. The average person's diet does not consist of these entirely, but the user of tobacco is in constant contact with arsenic.

This paper will present an analysis of cigarettes, cigars, snuff, chewing tobacco and smoking tobacco, purchased on the open market, and show that they all contain arsenic. It will also demonstrate that cigaret smoke contains arsenic in a form which may be taken up by the human body. It will present a series of cases of arsenical exfoliative dermatitis believed to be due to tobacco. A series of control cases will also be presented. It will attempt to show that the arsenic in tobacco has a very detrimental effect on the patient under anti-syphilitic treatment who happens to get a postarsphenamine dermatitis.

PROCEDURE

The Gutzeit test for arsenic has been used entirely in this experiment. The blood determinations have been made on 5 cc. of citrated blood. The tobacco tested that did not contain arsenic was obtained from a farmer who was known not to have used lead arsenate on his crop.

"Bakers analyzed" chemicals with a low arsenic content have been used throughout. Also control tests with the chemicals have been made on each analysis.

Figure 1 is the diagram of a mechanical smoker used for the determination of arsenic in cigaret smoke. It consists simply of two large test tubes connected by glass and rubber tubing and attached to a suction apparatus. A cigaret holder in one end was used to hold the cigaret that was being smoked. Distilled water was used as a solvent in both tubes. The water was analyzed for arsenic after ten, twenty, thirty and forty cigarettes of each of the five brands tested had been smoked. It is of importance to note here that the figures obtained from the analysis for arsenic from the mechanical smoker would not necessarily apply to the

Fig. 1.—Diagram of mechanical smoker used to show that cigaret smoke contains arsenic: The suction apparatus is turned on. The cigaret is then placed in the holder and lighted. The smoke is allowed to bubble through the distilled water in both tubes. The distilled water is analyzed for arsenic after ten, twenty, thirty and forty cigarettes of each of the five brands tested have been smoked.

human being. The mechanical smoker smoked each cigaret continuously. The human being does not do this.

RESULTS OF TOBACCO ANALYSIS

Table 1 shows the amount of arsenic found in the various types of tobacco. A control test was made on tobacco obtained from a farmer who had used no insecticide. It was negative for arsenic.

The arsenic content of the five brands of cigarettes tested was practically the same. One cigaret might show more arsenic than another but when the average is taken the figures are more or less constant.

In discussing this matter of arsenic with various research chemists of the tobacco companies I find that they have known for years that tobacco contained arsenic. They have more accurate analysis than I have,

Fig. 2.—Graph showing that arsenic content of distilled water of the mechanical smoker is in proportion to the number of cigarettes smoked.

but they tell me that these figures are approximately correct. They also say that lead arsenate is more or less used throughout where American tobacco is raised. I was told by one chemist that Turkish tobacco could be washed, which cannot be done with the domestic weed.

Table 2 shows the amount of arsenic found in the distilled water of the mechanical smoker after it had smoked ten, twenty, thirty and forty cigarettes of each of the five brands tested. The analysis of the smoke from twenty cigarettes of brand 2 was checked by Dr. W. E. Bray of the University of Virginia, who reported 0.0112 mg. of arsenic. The smoke from twenty cigarettes made of tobacco on which no lead arsenate had been used was negative for arsenic.

Figure 2 shows that the arsenic content of the distilled water of the mechanical smoker increased in proportion to the number of cigarettes smoked. All these figures are probably higher than the actual amount of arsenic consumed by the smoker. It is reasonable to conclude that the more one smokes the more arsenic one's body takes up. The distilled water was purposely used as a solvent in the mechanical smoker because it is the simplest one available.

CASES OF ARSENICAL DERMATITIS

Table 3 is a summary of the cases of arsenical dermatitis thought to be due to tobacco. Because of the lack of space these cases cannot be reported in detail, so only the pertinent facts in relation to each will be mentioned.

All of these cases showed either a positive blood or urine arsenic. Clinically, it can be said that the dermatitis could have been due to arsenic. In none of them was it possible to determine any source of arsenic other than tobacco. In some of these cases intravenous injections of calcium thiosulfate, along with mild sooth-

ing ointments and baths, were used, which is believed not to have had an appreciable effect. All the patients were emphatically cautioned against the use of tobacco and they recovered and have remained so since. Three of them have had mild recurrences every time they used tobacco.

TABLE 1.—Amount of Arsenic in Tobacco

Type of Tobacco	Milligrams of Arsenic				
	Brand 1 0.0426 mg. per cigaret	Brand 2 0.0465 mg. per cigaret	Brand 3 0.0420 mg. per cigaret	Brand 4 0.0365 mg. per cigaret	Brand 5 0.0495 mg. per cigaret
Cigarets *.....					
Cigars.....	Brand 1 0.08 mg. per cigar	Brand 2 0.088 mg. per cigar			
Snuff.....	2.60 mg. of arsenic per 100 Gm. of snuff				
Chewing tobacco..	1.60 mg. of arsenic per 100 Gm. of tobacco				
Smoking tobacco..	4.00 mg. of arsenic per 100 Gm. of tobacco				
Control tobacco..	Negative for arsenic				

* Each figure represents the average analysis of from 5 to 8 cigarettes on each brand.
† This is cured tobacco obtained from a farmer who had used no insecticide (lead arsenate) on his crop.

Patient 3 is of especial interest because he was the first one seen and also because he made his own diagnosis. When he first came in he stated that he believed his condition was due to smoking. At that time I tried to convince him that I did not think tobacco was responsible. It was several months later that another similar case was seen and the original one recalled. He was then asked to return to the office and a more detailed history was obtained. He stated that the more he smoked the worse the cutaneous condition became. He had also made the observation that he could smoke cigarettes that he himself made of tobacco on which no lead arsenate had been used. When asked if he used lead arsenate on his own tobacco, he said that he had not done so for a good many years because when he did it made him sick and also caused his skin to break out and itch as it does now. This patient still had his dermatitis when seen at the second visit. He was also smoking. His blood arsenic was positive. He was asked to refrain from the use of tobacco entirely and within

There are four cases reported as moderate. Itching and erythema of the skin were present in all. The type of eruption was the one frequently seen following the injection of an arsenical.

There are two cases reported as severe. In both there was a generalized erythema of the skin with marked exfoliation. It is a type which is frequently seen in a patient under antisyphilitic therapy when the attending physician does not stop the arsenical as soon as the dermatitis starts.

CONTROL CASES

Table 4 shows that the blood of six patients who had severe dermatoses, all smokers, was analyzed for arsenic and found to be normal. The reason for this is to attempt to prove that arsenic is not retained in the blood as a result of impaired secretion from a severe dermatitis, but that when the blood test does show arsenic it can be relied on to indicate the etiologic agent. The blood of three moderate smokers and three heavy smokers, all apparently normal physically, has been analyzed for arsenic and found to be negative.

Case 1 deserves some mention because it was seen about the same time as the investigation on the two original cases was being made. It almost made me give up the whole idea. The patient came in with a severe

TABLE 3.—Cases of Arsenical Dermatitis

Case	Degree of Cutaneous Involvement	Blood Arsenic, Mg. per 100 Cc.	Urine Arsenic, Mg. per 100 Cc.	Progress of Case	Source of Arsenic	Final Blood Arsenic
1. R. W. C.	Severe	0.002	0.06	Well	Cigarets	Negative
2. R. H. D.	Severe	0.125	Well	Cigarets	Negative
3. C. T. C.	Moderate	0.240	Well	Cigarets	
4. L. R.	Moderate	0.020	Well	Snuff	Negative
5. L. J. H.	Mild	Negative	0.002	Well	Cigarets	
6. W. N. V.	Moderate	0.040	Well	Cigarets	
7. H. H. E.	Moderate	0.006	Well	Pipe and chewing tobacco	
8. E. S. S.	Mild	0.000	Well	Cigarets	Negative

exfoliative dermatitis which from its appearance was surely thought to be arsenical. Repeated blood tests were negative for arsenic. The patient used snuff freely. After several weeks it was decided that there must be some other cause. The history was obtained that she had been taking a drug for high blood pressure. Communication with her physician determined this drug to be sodium thiocyanate. She responded when the drug was removed. About six months later she went to another physician for treatment of her hypertension and he, not knowing about her sensitivity to the drug, placed her on it again. She immediately broke out in the same manner as previously. She again responded after the drug had been stopped. She had a positive patch test to sodium thiocyanate and a negative patch test to lead arsenate.

EFFECT OF TOBACCO ON POSTARSPHENAMINE DERMATITIS

Table 5 shows a series of four cases of dermatitis following neoarsphenamine in which it is thought that tobacco has been detrimental to the recovery. From the history and my own observations it is believed that the antisyphilitic drug was stopped immediately on the first sign of skin involvement.

Patient 1 was referred because of a slight itching following the sixth injection of neoarsphenamine. Both the physician and the patient stated that there had been no untoward reaction previously. In spite of this fact,

TABLE 2.—Amount of Arsenic Found in the Smoke of Five Popular Brands of Cigarets

Cigaret	Number of Cigarets Smoked			
	10	20	30	40
Brand 1.....	0.004 mg.	0.006 mg.	0.008 mg.	0.014 mg.
Brand 2.....	0.008 mg.	0.014 mg.	0.010 mg.	0.020 mg.
Brand 3.....	0.004 mg.	0.014 mg.	0.018 mg.	0.020 mg.
Brand 4.....	0.002 mg.	0.008 mg.	0.012 mg.	0.018 mg.
Brand 5.....	0.004 mg.	0.004 mg.	0.016 mg.	0.020 mg.

Analysis of the smoke from twenty cigarettes of brand 2 was checked by Dr. W. E. Bray of the University of Virginia, who reported 0.012 mg. of arsenic. The smoke from twenty cigarettes made of tobacco on which no insecticide (lead arsenate) had been used was negative for arsenic.

three weeks he was well. He has since been able to smoke continuously cigarettes made of his own tobacco on which no insecticide had been used.

There are two cases reported as mild, by which I mean a generalized dry skin with only slight exfoliation and slight redness. The symptom of itching brought these patients to the office rather than their anxiety over the dermatitis. The eruption was of comparatively short duration.

the man's condition rapidly became worse and it was only after six weeks of observation, when the patient's condition had reached the point where it was thought that he was going to die, that tobacco was discontinued. In less than one month's time he was well.

Patient 2 was a colored girl who had a mild cutaneous rash following the third injection of neoarsphenamine. The treatment was discontinued and in about three weeks' time her skin was entirely normal. She was then lost track of and was not seen again for eight months, at which time she had a moderately severe exfoliative dermatitis of three weeks' duration. She had had no further antisyphilitic treatment of any kind, but for three months previous to this recurrence she had been using snuff. Her blood was positive for arsenic. She had a positive patch test to 1:10,000 solution of neoarsphenamine and lead arsenate. The snuff was discontinued and in six weeks her skin was apparently normal.

Patient 3 is a colored man who was under observation in the clinic. He had a mild dermatitis following the third injection of neoarsphenamine. The drug was stopped immediately. He had had no previous itching. He was told to discontinue the use of tobacco, but he did not. He was not seen until two months later, at which time he had a severe exfoliative dermatitis. He was immediately hospitalized and for the past three months his condition has been gradually improving. However, although at the present time he is very much better he still shows a slight trace of arsenic in

the fact that she had received a total of only 0.4 Gm. of neoarsphenamine, her condition progressed. She died with what is now believed to have been a condition due to arsenic in tobacco. It is thought that no person who gets a postarsphenamine dermatitis should use tobacco.

TABLE 5.—*Tobacco and Postarsphenamine Dermatitis*

Case	Diagnosis	Initial Blood Arsenic, Mg. per 100 Cc.	Final Blood Arsenic, Mg. per 100 Cc.	Comment
1. J. F.	Arsenical dermatitis	0.040	Negative	Cutaneous condition progressed until tobacco was stopped
2. M. H.	Arsenical dermatitis	0.080	Negative	Arsenical dermatitis healed; recurred with snuff habit
3. C. W.	Arsenical dermatitis	0.600	0.006	Cutaneous condition progressed until tobacco was stopped
4. A. S.	Arsenical dermatitis	Not done	Not done	Patient died in 1936; tobacco not thought of then

It is believed that any person under syphilitic therapy who gets a postarsphenamine dermatitis should not use tobacco in any form.

SUMMARY

It has been proved by other workers and myself that tobacco contains arsenic. It is common knowledge to those living in a tobacco section that farmers freely use lead arsenate as an insecticide to kill the horn worm. Nothing has been done or probably can be done in either the agricultural or manufacturing process to remove it. A series of cases with exfoliative dermatitis and positive blood arsenic, whose sources of arsenic were thought to be tobacco, was observed. The blood in a series of cases of severe dermatoses and normal individuals has been analyzed for arsenic and found to be negative, even though the subjects were heavy smokers. It is thought that there is a sufficient amount of arsenic in tobacco to have a very detrimental effect in cases of postarsphenamine dermatitis.

It is realized that the Gutzeit test may not be sensitive enough to determine a difference in the blood arsenic of smokers and nonsmokers.

It is believed that patients get this dermatitis because they are hypersensitive or allergic to arsenic.

This paper has attempted to present a theory. Its ultimate proof depends on the collaboration of other workers.

ABSTRACT OF DISCUSSION

DR. DUDLEY C. SMITH, Charlottesville, Va.: Dr. Barksdale's presentation calls attention first to an etiologic factor in some skin diseases and second to a contributing cause to untoward reactions in the modern treatment of syphilis. In persons hypersensitive to arsenic, enough of the substance can be introduced into the body by the use of tobacco to cause inflammatory changes in the skin. It is interesting to speculate how much effect occurs in other tissues, such as the kidneys or brain or aorta or the coronary vessels. Trivalent arsenic has an affinity for small arterioles and capillaries and thus may cause severe dermatitis, hemorrhagic encephalitis, purpura and possibly coronary disease. Pentavalent arsenic has affinity for structures of ectodermal origin. The taking of arsenic into the body from tobacco over a period of time may sensitize the tissues to this chemical, thereby causing from the same source later or preparing the basis for toxemia from other substances like arsphenamine. This work gives the dermatologist and syphilologist another bit of knowledge which will help to clarify the etiology of cutaneous eruptions and to prevent the all too prevalent

TABLE 4.—*Control Cases*

Case	Diagnosis	Blood Arsenic	Final Status
1. R. C. C.	Exfoliative dermatitis	Negative	Used snuff but was allergic to sodium thiocyanate taken for high blood pressure
2. D. W. P.	Exfoliative dermatitis	Negative	Apparently followed a seborrheic dermatitis; smoked and chewed
3. E. T. D.	Infectious eczematoid dermatitis	Negative	Heavy smoker but cleared up on removal of abscessed teeth
4. J. S. M.	Infectious eczematoid dermatitis	Negative	Heavy smoker but well after treatment for acute tonsillitis
5. J. G. C.	Infectious eczematoid dermatitis	Negative	Heavy smoker but cleared up on removal of abscessed teeth
6. J. A. R.	Acute disseminated lupus erythematosus	Negative	Smoked, had marked exfoliation and pregnancy; patient died
7. G. D. J.	Normal control	Negative	Moderate smoker
8. M. E. T.	Normal control	Negative	Moderate smoker
9. R. M. D.	Normal control	Negative	Moderate smoker
10. J. H. P.	Normal control	Negative	Heavy smoker
11. H. V. A.	Normal control	Negative	Heavy smoker
12. E. E. B.	Normal control	Negative	Heavy smoker

his blood. It is believed that the postarsphenamine dermatitis that this man had would have healed promptly if all the sources of arsenic had been removed.

Case 4 is one that is reviewed in retrospect. The patient was seen in 1936, at which time I did not realize that tobacco contained arsenic. She used snuff freely. She was referred to me by a physician who stated that her dermatitis began following the second injection of 0.2 Gm. of neoarsphenamine. I have since come to learn that this physician's statements are reliable. In spite of

untoward reactions in the therapy of syphilis. In cases of erythematous eczema and persistent erythema multiforme, it might be worth while to eliminate the use of tobacco as a therapeutic test. It is definitely indicated that tobacco be discontinued by patients receiving antisyphilitic treatment. This is a more theoretical than practical suggestion, because few people will follow this direction. The development of a spray which the farmers can use on tobacco which would be cheap and at the same time easily applied would, of course, correct this condition. It is an honor to open the discussion on this presentation, which has just received a certificate of merit in the Scientific Exhibit.

DR. HARRY M. ROBINSON, Baltimore: Dr. Barksdale's paper presents an interesting premise which I think should be kept in mind as a possible factor causing persistence or recurrence of the eruption in postarsphenamine dermatitis. In my experience with 350 cases of postarsphenamine dermatitis, complete involution occurred in all the patients except the few that died, through treatment with simple antipruritic applications and supportive care, including intravenous injections of dextrose solution. In one of the patients the eruption recurred once after apparent complete involution, although no arsenic or other heavy metal in any form was being administered. In two others the eruption persisted somewhat longer than the usual run of cases, but in these as well as in all the others final involution eventually was brought about without difficulty and without enlisting the aid of such elements as Dr. Barksdale has mentioned: this in spite of the fact that almost all the patients, male and female, were smokers and generally indulged in smoking during and after convalescence. Two of the patients were sensitive to trivalent and pentavalent arsenicals, including potassium arsenite. When Dr. Barksdale told me of his report, I sent for some of my postarsphenamine exfoliative dermatitis patients and three returned, one Negro woman and two white men. These I examined with patch tests for sensitivity to neoarsphenamine, a popular brand of cigaret tobacco and dried Maryland tobacco leaf which had been obtained from a storage room. This tobacco leaf was assayed for arsenic and contained 6 micrograms per gram, which is about the normal amount of arsenic contained in tobacco. The Negro woman was positive to the patch test with Maryland tobacco leaf but not to the 30 per cent solution of neoarsphenamine or to the cigaret tobacco. One white man was strongly positive to the neoarsphenamine but not to either tobacco. The third patient did not react positively to any of the tests. I realize that the results of these tests have no significance, as all three patients smoked and none had any residual eruption at the time of testing, although all three had had severe types of the eruption, necessitating hospitalization. If I encounter cases of postarsphenamine dermatitis which do not involute in a reasonable time I shall attempt to determine the effect of tobacco or other elements as possible aggravating factors.

DR. MARION B. SULZBERGER, New York: In the arsphenamine sensitization which I have studied, while a few patients have been hypersensitive to arsenic the vast majority are not hypersensitive to the element arsenic at all. They are sensitive to trivalent arsenicals but not to trivalent arsenic as such, but to trivalent arsenic in an organic, benzolic combination. This can be demonstrated, for example, by their lack of clinical sensitivity to arsenic: one can often administer solution of potassium arsenite or sodium arsenate injections or even tryptarsamide and other arsenicals with impunity to patients who have arsphenamine dermatitis. So that at least in most cases of arsphenamine dermatitis—but not in all—there is no sensitivity to the element arsenic as such. When individuals react to cutaneous tests with tobacco, I found that it was always to something in the tobacco other than the nicotine. That is as far as I could go in conclusions with regard to vascular sensitivity to tobacco. This refers not to the type of sensitivity which one sees in dermatitis of the sort that Dr. Barksdale has been studying but to the vascular sensitivities which are demonstrable in many cases of Berger's disease (thrombo-angiitis obliterans) and in other persons in the form of wheal reactions to scratch or intracutaneous tests with tobacco extracts. The

opportunities for exposure to arsenic are numerous. This element occurs not only in tobacco but in beer, bread, wine, fruits and fish and has been known to occur in small quantities in volatile form and can be inhaled through the air. In certain districts, for example near smelting works, one finds a hundredfold increase in the amount of arsenic in the blood and urine of persons who live on the lee side of blast furnaces as compared with those on the windward side. It is also known that eating sea fish and especially shellfish will materially increase the arsenic levels of the blood and urine. It therefore seems that, if it were conceivable that arsphenamine dermatitis could be maintained by the arsenic in tobacco, we should have to be careful not only of smoking but also of the food and drink of these patients. I should like to ask Dr. Barksdale whether he performed patch tests in these particular cases with water through which he has bubbled the smoke of the tobacco in question; and, if so, what were the results? Did this water contain appreciable amounts of arsenic? And particularly did it elicit positive patch tests in his patients and no reactions in controls?

DR. HERMAN SHARLIT, New York: Those of us who think in terms of specific allergies are somewhat confused when we are presented with allergens in terms of a single source that may not be completely elucidative of the allergen involved. Apparently the reactions that are induced in the skin here are coming from elements that are volatilized in a combustion mixture of a temperature well above 400 centigrade. What the form of the arsenic is at the moment of volatilization and as passed on to the lung is difficult to say. We must consider whether this may not be a lead arsenic compound, for the lead too is volatilized and the lead too gets into the lungs. It is possible the lead, either alone or in combination with the arsenic, plus other volatiles might have to be present to induce the sensitization in these individuals. At any rate, the deductions from such an investigation, if they are to be maintained, for example the injunction that people who are being treated with arsphenamine should, if there is any evidence of a sensitization to the trivalent arsenic, stop smoking, are serious restrictions for those who enjoy smoking. It would therefore be necessary to follow this through with a greater elucidation of the elements involved. I would be anxious to know, as Dr. Sulzberger suggested, what was contained in the water extract of the smoke. And in making these analyses in blood and urine, the lead also should be taken into consideration. One will realize in looking over the arsenic figures in the blood, as given in the tables, that they varied from a significant figure in the first to one in the third decimal place. That is a range of a hundredfold variation, with no apparent correlation with the clinical observations. Then many of the records indicated that there was no arsenic. I have had the impression that to find no arsenic in the blood is almost as rare as finding a high arsenic in the blood. There are still many hiatuses in leading to a conclusion with respect to whether it is arsenic alone that caused these disabilities.

DR. E. E. BARKSDALE, Danville, Va.: I appreciate the discussion and I have learned more probably than any one else. There are many facts in this experiment that need further investigation; unfortunately it was necessary to do this work in a small private laboratory with extremely limited facilities. I have been asked to explain the negative blood test. It is true that there is no such thing as a negative blood arsenic. In this work we have called the blood arsenic of normal individuals negative even though they might show a small trace of arsenic. While there is a large personal factor involved in reading the Gutzeit test, we have not called any of them positive unless they were definite. Dr. Robinson stated that he had not been able to obtain a positive patch test with tobacco; neither have I. The only positive patch tests in these cases have been obtained from lead arsenate itself. We have not done patch tests with distilled water of the mechanical smoker through which tobacco smoke has been bubbled; it brings up an interesting problem. I have used the word "hypersensitive" or "allergic" to explain these cases; I think a more descriptive phrase would be a "point of tolerance." Some people have a very low point of tolerance to arsenic. Fortunately, the point of tolerance for arsenic of most persons is much higher than the amount of arsenic that one could consume from tobacco.

MALARIA AND ARTIFICIAL FEVER IN THE TREATMENT OF PARESIS

PAUL A. O'LEARY, M.D., ROCHESTER, MINN., CHAIRMAN;
WALTER L. BRUETSCH, M.D., INDIANAPOLIS, FRANKLIN G. EBAUGH, M.D., DENVER, WALTER M. SIMPSON, M.D., DAYTON, OHIO, HARRY C. SOLOMON, M.D., BOSTON, STAFFORD L. WARREN, M.D., ROCHESTER, N. Y., FOR THE COOPERATING CLINICS AND R. A. VONDERLEHR, M.D., LIDA J. USILTON, M.A., AND I. V. SOLLINS, PH.D., WASHINGTON, D. C., FOR THE U. S. PUBLIC HEALTH SERVICE

During the past two decades the widespread therapeutic use of malaria gave rise to the consideration of other pyrexial methods for the treatment of paresis. The present study has been designed to compare the therapeutic results obtained by use of artificial fever produced by physical methods with those obtained by the use of inoculated malaria in the treatment of paresis. These two methods of fever therapy were employed independently or in association with some form of chemotherapy and have been evaluated in terms of the clinical and serologic response observed in the patients. The effects of chemotherapy alone have not been evaluated.

Total	1,100	100.0	320	100.0

THE DATA

A total of 1,420 patient records were pooled for this study. Of these, 1,100 patients were treated with malaria and 320 with artificial fever.

Prior to the administration of fever therapy, the diagnosis of paresis or of taboparesis was established for each patient. In evaluating the results of therapy among patients with taboparesis, only the responses of the paretic symptoms to the therapy have been considered.

The study was limited to patients with paresis followed two years or more after the beginning of fever therapy (table 1). The median age for all paretics in this series was 41.5 years when fever therapy was instituted. The average difference in age between patients with mild and those with severe paresis was approximately four years, the patients with mild paresis being the younger. The intermediate group stood mid-

way in age between the mild and the severe. There was no age selection of candidates for one or the other type of fever therapy.

DEFINITIONS

The term "paresis" in this study refers to the symptom complex caused by syphilitic meningo-encephalitis, characterized by distinctive psychiatric, neurologic, serologic and spinal fluid abnormalities.

All patients were classified by degree of involvement on beginning treatment with fever therapy. The following subdivisions were maintained throughout the evaluation:

(a) Mild: Relatively free from signs of deterioration, with mental symptoms, usually transitory.

(b) Intermediate: Symptoms of manic excitement, depression or other psychiatric syndromes, in addition to evidence of moderate deterioration.

(c) Severe: Evidence of advanced deterioration.

The clinical results of therapy were defined as:

(a) Remission: Sufficient clinical recovery to permit the patient to return to his former socio-economic status.

(b) Improved: Complete or partial disappearance of clinical manifestations without corresponding improvement in the capacity to return to the former socio-economic status.

(c) Unimproved: No detectable clinical evidence of change in the course of the disease.

(d) Progressed: Clinical condition less satisfactory after therapy than before.

(e) Death: Treatment deaths during therapy, or deaths regardless of cause, occurring during or within three months subsequent to therapy.

Occasionally, further grouping of the cases in terms of clinical results was necessary in order to effect additional comparisons. These groups were:

(a) Clinical success: Remission.

(b) Clinical failure: Unimproved, progressed, death.

(c) Relapse: Reversal from a clinically successful result to a clinical failure.

The serologic results of therapy, as determined by spinal fluid and blood tests, were classed as:

(a) Positive (which includes cases with doubtful reactions).

(b) Negative.

(c) Not done.

The various degrees of abnormality of the spinal fluids were classed as:

(a) Group 1 (mildly positive): Spinal fluid in which the cell count was 10 or more, positive globulin test, with complement fixation or flocculation test negative or positive, and colloidal tests negative.

(b) Group 2 (moderately positive): Spinal fluid in which the cell count and globulin content were increased, with complement fixation or flocculation tests positive or weakly positive, and the colloidal test indeterminate or of the so-called luetic type.

(c) Group 3 (strongly positive): Spinal fluid in which the observations conformed to the so-called paretic formula, i. e. marked excess of globulin, strongly positive complement fixation results (at 0.2 cc. or less) or strongly positive flocculation tests, the paretic type curve on the colloidal test, and an increased cell count which may contain, in addition to small lymphocytes, large leukocytes and polymorphonuclear leukocytes.

(d) Group unknown: Spinal fluid in which the complement fixation or flocculation result was positive but results of other tests were unknown.

CLINICAL RESULTS

Yearly clinical remission rates were cumulated per hundred patients treated by method of therapy and degree of involvement of the paresis on beginning fever

Conducted by the cooperation of the Mayo Clinic, Rochester, Minn.; Central State Hospital, Indianapolis; Colorado Psychopathic Hospital, Denver; Miami Valley Hospital, Dayton, Ohio; Boston Psychopathic Hospital, and Strong Memorial Hospital, Rochester, N. Y. In addition to records from the institutions of the authors, the following clinic chiefs offered for analysis the records from their institutions: A. E. Bennett, M.D., Bishop Clarkson Memorial Hospital, Omaha; Harold N. Cole, M.D., Cleveland City and University Hospitals of Western Reserve University; J. R. Blalock, M.D., and Leland E. Hinsie, M.D., New York State Psychiatric Institute and Hospital; Frank R. Menagh, M.D., Henry Ford Hospital, Detroit, and Ernest H. Parsons, Fitzsimons General Hospital, Denver. The Committee acknowledges the preliminary statistical preparation of the material by Albert P. Iskrent, A.B., U. S. Public Health Service.

therapy. The total successful results of therapy are shown at the conclusion of any given year within the entire duration of treatment-observation. The increase in the successful outcomes of therapy within a given year may be obtained by subtraction (table 2).

Among the patients with mild and intermediate paresis there were no statistically significant differences

between the rates of remission obtained under malaria and those obtained under artificial fever therapy. Sharp and statistically reliable differences were noted between the results of the two methods of therapy among patients with severe paresis on beginning treatment.

The superiority of remission rates obtained under artificial fever therapy in patients with severe paresis but not in those with mild or intermediate paresis led to a complete review of the records by one of us (H. C. Solomon). This uniform classification of patients by degree of involvement of paresis on beginning treatment confirmed the original observations.

The earlier in the course of the disease the fever therapy was instituted, the more favorable were the clinical results. By the conclusion of three or four years of treatment-observation, more than one half the patients with mild paresis treated with either method of therapy had clinical remissions. The chances of clinical recovery with either method of therapy were reduced to approximately one in four for patients with intermediate paresis. The remission rates for patients with severe paresis, treated and observed for the same length of time, decreased to approximately one in a hundred under malaria and ten in a hundred under artificial fever (table 2). Proportionately more clinical progressions occurred in patients with severe paresis under malaria than under artificial fever therapy. Except for the better clinical response to artificial fever in patients with severe paresis (more clinical remissions and fewer clinical progressions) there were no other statistically reliable differences in the clinical results obtained with the two types of therapy (table 3).

For purposes of this study, we defined as treatment deaths not only patients who died during fever therapy but also those who died regardless of cause within three months of treatment. Under this definition the total crude death rate was higher with malaria (13 per cent) than with artificial fever (8 per cent). A subdivision of the material by degree of involvement of paresis prior to fever therapy indicates that the more severe the paresis the higher the frequency of death (table 4). This was true of patients treated with either type of fever therapy. Within each degree of involvement the percentage of deaths was higher under malaria than under artificial fever therapy. Although these individual differences were not statistically significant in

themselves, they all point in the same direction. Had sufficient material been available, a more definite statement as to the relative frequency of death under these two methods of treatment might have been possible through the construction of a death curve for the paretic. Such a death curve compared with that for the general population would have eliminated some of the uncontrolled factors in the present investigation.

The relative speed with which remissions were obtained was determined on the basis of all cases treated and observed for two or more years. To determine the speed of remission, the data were not limited to cases under treatment-observation for three or four year periods, because cases more resistant to treatment tended to remain under observation, while those less resistant disappeared earlier. Of the total remissions obtained under either method of therapy, approximately 90 per cent of the successful results occurred by the end of the third year. The degree of paretic involvement on beginning fever therapy influenced the frequency and speed of expected remissions. Remissions were obtained from one to two years earlier in mild than in intermediate or severe paresis.

None of the patients in whom clinical improvement was delayed until the third year after beginning therapy at any time reached the remission stage. Of the 432 with clinical improvement during the first or second year after beginning fever therapy, subsequent clinical remissions were obtained in 34 per cent of those with clinical improvement the first year and 12 per cent of those in whom clinical improvement was delayed until the second year. Therefore the earlier the positive clinical response was obtained, the better were the prospects for eventual remission.

Once a complete remission had been obtained, the chances of its being maintained were 95 out of 100. In the malaria-treated group 3.3 per cent and in the artificial fever group 5.5 per cent of the remissions subsequently relapsed. The available data show that fifteen of a total of seventeen relapses occurred within

* Including treatment deaths and deaths within three months of treatment.

three years subsequent to the year of remission. The highest percentage of relapses occurred among the patients with severe paresis. The differences in the relapse rates of the two methods of fever therapy were not statistically significant.

SEROLOGIC RESULTS

Laboratory data, consisting of at least one pretherapy and one posttherapy spinal fluid and blood examination, were available for only one half to three fourths of the

1,100 cases treated with malaria and for from 75 to 90 per cent of the 320 cases treated with artificial fever. It was assumed that the standards and technics of laboratory testing were comparable in the several clinics cooperating in this study.

Regardless of the method of therapy, the percentages of reversal both in spinal fluid and in blood increased

too few to permit the establishment of satisfactory statistical differences, but those treated with tryparsamide and a heavy metal represented a sufficient number for this purpose. The percentages of spinal fluid and blood serologic reversals obtained through treatment with malaria plus tryparsamide were significantly higher than those obtained with artificial fever plus tryparsamide.

Twice as high a proportion of patients experienced blood and spinal fluid reversals when chemotherapy was employed with malaria as when similar forms of chemotherapy were used with artificial fever. The amount of such chemotherapy administered to each fever group was evaluated. For this purpose treatment with various forms of chemotherapy was reduced to "chemotherapeutic units" based on the following assumptions:

- 1 injection of a trivalent arsenical, 1 treatment unit.
- 1 injection of a pentavalent arsenical (tryparsamide), 1 treatment unit.
- 0.35 intraspinal treatment, 1 treatment unit.

Recognizing that the analysis is based on an arbitrary assumption of "chemotherapeutic units," the apparent superiority in spinal fluid reversal rates of the malaria patients treated with auxiliary chemotherapy suggests association with a greater amount of chemotherapy administered. By the end of the third year the patients with spinal fluid reversals treated with malaria had received 17 per cent more chemotherapy than those treated with artificial fever therapy.

Chemotherapy, auxiliary to either type of fever therapy, appeared necessary not only to obtain a higher percentage of spinal fluid reversals but also to maintain these reversals. Among patients not treated with auxiliary chemotherapy, approximately 42 per cent of all spinal fluid reversals subsequently relapsed, as compared with only 24 per cent spinal fluid relapses in cases treated with auxiliary chemotherapy. Two thirds of all the spinal fluid relapses, regardless of whether or not chemotherapy was employed, occurred within one year following the original reversal.

as the duration of treatment-observation grew longer. Spinal fluid reversal rates at the conclusion of each of four annual periods were not only more rapid but approximately twice as frequent under malaria as under artificial fever. Positive blood reversed more rapidly though not in greater proportion than positive spinal fluid. The percentage of blood reversals was greater in the malaria-treated group but not so rapid as in the artificial fever group.

These differences in serologic response to the two methods of therapy were further investigated as to the abnormality of spinal fluid prior to fever therapy and to the influence of chemotherapeutic agents.

The more abnormal the spinal fluid the less responsive it was to any type of treatment. However, it was found that proportionately as many patients treated with malaria as with artificial fever had strongly abnormal (paretic type) spinal fluid. Therefore, any increase in the spinal fluid reversal rate in the malaria-treated patients was not due to favorable differences in the pretherapy abnormality of spinal fluid in that group.

To determine the effect of chemotherapy, the patients under study were divided into two major groups: those receiving no chemotherapy and those who were given chemotherapy in addition to or in connection with fever therapy. Since the spinal fluid rates were influenced by the duration of the treatment-observation period, the comparison was confined to the status of the spinal fluid and blood during the third year of treatment-observation of patients who were observed for three or more years.

The percentages of spinal fluid and blood reversals in the malaria and artificial fever therapy patients not receiving chemotherapy were similar. None of the differences were statistically significant. Among those patients treated with chemotherapy better results were observed in the malaria than in the artificial fever group. These were statistically significant (table 5).

In evaluating the specific arsenical used in conjunction with fever therapy it was found that the number of patients treated with arsphenamine only, or with the combination of arsphenamine and tryparsamide, were

TABLE 5.—*Posttherapy Status of Originally Positive Spinal Fluids and Blood After Three Years of Treatment—Observation in Paretic Patients Treated with Fever Only and with Fever Plus Chemotherapy*

Method of Therapy	Posttherapy Status			
	Spinal Fluids		Blood	
	Per Cent of Negative	Total Cases of Positive	Per Cent of Negative	Total Cases of Positive
Malaria only.....	5.8	91.2	15.9	81.1
Artificial fever only.....	11.1	88.9	13.5	86.5
Total fever only.....	6.7	93.3	15.4	84.6
Malaria plus chemotherapy.....	29.6	70.4	30.6	69.4
Artificial fever plus chemotherapy.....	14.3	85.7	13.6	86.4
Total fever plus chemotherapy.....	23.3	74.5	25.4	74.6

The significance of the blood was studied as an indication of the spinal fluid reaction. Of patients with originally positive blood and spinal fluids, on termination of four years' treatment-observation, only 15 per cent had obtained a reversal of both the blood and the spinal fluid, whereas of 63 per cent the blood and spinal fluid remained positive. Therefore a negative blood did not indicate the status of the spinal fluid but a persistently positive blood was frequently indicative of a positive spinal fluid.

Clinical Notes, Suggestions and New Instruments

MULTIPLE LACERATIONS OF MUCOSA OF THE RECTUM AND SIGMOID FROM A FOREIGN BODY INGESTED WITH GRAPE JELLY

MORTIMER DIAMOND, M.D., CHICAGO

One of the most interesting phases of proctology is the subject of foreign bodies. The literature contains numerous reports of the recovery of these objects from the rectum and the sigmoid, where either they gain entrance by ingestion, by introduction through the anal canal or by perforation from an adjacent viscus, or they form in situ. Of these the oral route is the commonest, and though the ingestion is usually accidental it may be intentional for purposes of concealment, suicide or entertainment. In many instances the patient is conscious of the fact that he swallowed the object, but often he is unaware of this for it may occur during anesthesia, intoxication or other semistuporous states.

One is amazed by the variety and number of ingested objects that have been removed from the rectum. Gant¹ mentions more than fifty different kinds, and a complete list very likely would include many more. Probably the largest number of foreign bodies ever removed were a group of 1,874 cherry pits impacted in the rectum of a man 37 years old. This case was reported by Falk² in 1915. The patient complained of gradually increasing constipation, swelling of the abdomen and finally diarrhea. Examination revealed the impaction in the rectum, from which 897 pits were removed digitally. The next day an additional 399 were obtained, and one hour later the patient passed 578 more. He had been eating cherries during that entire summer and had not taken the trouble to remove the pits.

Foreign bodies may pass through the gastrointestinal tract without causing any trouble. This often is the case when the object is small and smooth, as a bead, marble or button. However, when it is larger disturbances usually develop, the clinical picture produced being dependent on the physical characteristics of the object in question and the segment of the gastrointestinal tract involved.

A large foreign body such as a ball, key or set of teeth may cause pain as it is swallowed, epigastric distress and vomiting when in the stomach and abdominal cramps while going through the intestine. Although complete obstruction is infrequently produced, interference with the passage of the contents through the gastrointestinal tract is not uncommon, occurring when the object becomes lodged at some point. The most frequent sites are the esophagus, the pylorus, the duodenum, the ileocecal region, the rectosigmoid juncture and the lower part of the rectum.

If the object is sharp like a pin, a fish bone or a piece of glass it may lacerate the mucosa to cause bleeding or it may perforate the bowel and lead to infection, abscess, fistula or peritonitis. When the lacerations are large or numerous, sufficient blood will be lost to color the stool.

With a foreign body in the rectum the patient may experience a sense of pressure, weight or fullness associated with a desire for a bowel movement, which will be difficult if the object is large, and painful and associated with bleeding if it is sharp and lacerates the anal canal while being expelled. Occasionally the foreign body forms a nucleus around which feces collect and inspissate. In these cases constipation gradually becomes more marked, and eventually a stercoral type of diarrhea may develop.

As a rule it is not very difficult to find a foreign body in the rectum. At times it can be seen protruding through the anus. Usually it can be found on digital examination. When it is beyond the reach of the finger, the routine proctoscopic

and sigmoidoscopic examination will reveal it and the injuries of the mucosa that may be present. One should not overlook a small foreign body, which may be caught in an anal crypt or on the superior surface of a valve of Houston. Roentgenologic examination of the colon is important in locating those foreign bodies beyond the reach of the sigmoidoscope. Often more difficulty is encountered in the removal of the object than in the diagnosis, and much ingenuity may be required to accomplish this successfully.

The following report makes an interesting addition to the list of unusual ingested foreign bodies which cause multiple lacerations of the mucosa of the rectum and sigmoid with rectal bleeding. A review of the literature fails to reveal an account of a similar case.

REPORT OF CASE

On March 19, 1936, Dr. N. consulted me about Mrs. N. T., a white woman aged 38, who complained of abdominal cramps and bloody bowel movements. Six days previously she had eaten some grape jelly that seemed gritty. The following day while she was eating more of the same jelly something cut her tongue and caused it to bleed. She removed a sharp object from her tongue and on seeing it immediately called her physician, fearing that she had swallowed some glass. Vomiting and later abdominal pain developed and she began to pass bloody stools.

Dr. N. examined her, treated the tongue, prescribed a soft diet and liquid petrolatum and then examined the jelly. In it he found some flat, sharp, pointed, roughly triangular to spearhead shaped crystalline objects that were colorless to yellowish and up to one-fourth inch in longest dimension. He too thought that they were pieces of glass but for verification sent them to a chemist for analysis.

Because bloody stools continued to be passed, I was asked to make a proctologic examination. Except for a mildly tender abdomen the general physical picture was normal. Two linear lacerations approximately one-fourth inch long were seen in the skin of the outer portion of the anal canal. They were superficial, with thin edges and hemorrhagic bases. The tone of the anal muscles was increased and the anal canal was tender.

The mucosa of the lower 10 inches of the rectum and the sigmoid as seen through the proctoscope and sigmoidoscope presented a number of lacerations, some lying obliquely and others in the long axis of the bowel. They were up to 3 mm. deep and 13 mm. long, being most numerous in the lower part of the rectum. Some were irregular and others linear, and in the deeper ones were bits of sharp glasslike particles similar to those found in the jelly. The mucosa did not show any other changes.

The lesions in the mucosa were definitely lacerations and did not resemble the umbilicated ulcers of amebic dysentery, the elliptic ulcerations of tuberculosis of the bowel or the irregular secondary infected ulcers of chronic thrombo-ulcerative colitis.

From the definite history of laceration of the tongue while eating, the vomiting, the abdominal pains and the passage of bloody stools coupled with the lacerations in the mucosa of the rectum and the sigmoid, it was readily evident that the patient was suffering from the traumatic effects of the sharp foreign bodies which she had swallowed.

After continuation of the nonresidue diet, liquid petrolatum and antiseptic irrigations, the bleeding gradually subsided and the wounds healed.

COMMENT

The interesting feature in this case is the type of foreign body that was present in the jelly, for contrary to expectations the chemist, Mr. George Borrowman, reported that the objects were not pieces of glass but crystals of potassium bitartrate.

According to Sir Edward Thorpe,³ potassium bitartrate is a natural constituent of grape juice and because of its lesser solubility in alcohol is deposited on fermentation, partly as a crystalline crust (argol) and partly with the lees. Its solubility is diminished by the presence of tartaric acid, which

3. Thorpe, Sir Edward: *A Dictionary of Applied Chemistry*, London, Longmans, Green & Co., Ltd., 1926, vol. 6, p. 687.

also exists naturally in grape juice, and potassium sulfate, potassium nitrate and especially potassium chloride greatly reduce its solubility in water. Its crystals are aggregates of small hard rhombic prisms.⁴

The question "Why did crystallization take place?" naturally arises. Commercially, grape jelly is usually made not from whole grapes but from grape juice, which is taken from large storage tanks as needed. Perhaps some change occurred in the grape juice before it was processed into jelly. Bacterial fermentation with alcohol formation and crystallization is unlikely because the juice is stored at a low temperature. Autogenous enzyme action, however, might have changed the acidity of the juice, and perhaps in the concentration incident to jelly making crystallization followed. The question can be answered only after a careful investigation at the plant.

The question now arises, Can crystals of potassium bitartrate go through the entire gastrointestinal tract without being dissolved? This depends on (1) the number, the size and the solubility of the crystals, (2) the character, the composition and the pH of the intestinal contents and (3) the length of time in the intestinal tract. In one set of circumstances they may dissolve completely and in another they may not. In this case, however, it is apparent that complete solution did not occur because crystals were removed from the lacerations in the rectum.

Another matter of interest is the question whether or not there were any lacerations, in addition to those seen in the rectum and the sigmoid, in the rest of the gastrointestinal tract. One might expect that the soft contents of the upper intestinal canal would coat the crystals and prevent any damage to the mucosa. But in view of the vomiting, the epigastric distress, the abdominal cramps and the continued passage of bloody feces it is assumed that lacerations were probably present throughout the intestine.

CONCLUSIONS

An ingested foreign body may lacerate the mucosa of the rectum and the sigmoid and cause rectal bleeding.

A case of rectal bleeding was due to multiple lacerations from crystals of potassium bitartrate ingested with grape jelly.

58 East Washington Street.

AN ADDITIONAL PHYSICAL SIGN OF A MALIGNANT TUMOR OF THE BREAST

CLARENCE E. REES, M.D., SAN DIEGO, CALIF.

The characteristic fixation of malignant tumors of the breast either to the skin or to the fascia of the pectoralis major muscle is well known. This characteristic is due to the arrangement of the areolar tissue and of the capsule of the breast. The continuity of the stroma throughout the gland forms compartments for the secreting elements. Fibrous prolongations from the stroma of the breast connect the breast in its anterior portion with the under surface of the skin and in its posterior portion with the aponeurosis of the pectoralis major muscle. Thus all tissues surrounding the breast are bound to it by connective tissue fibers which are continuous with the matrix of the breast.

Because of this peculiar structure, a malignant tumor in the breast infiltrates the matrix and causes a contraction of its fibrous elements. This contraction produces an abnormal firmness in the area of involvement. As the process progresses this contraction radiates in all directions from the tumor and causes the tumor to become fixed to the surrounding structures. The fixation is first apparent in structures which lie nearest to the tumor mass. If the tumor is near the skin, the fixation first involves the skin; if it is central, fixation results in retraction of the nipple; if it is deep, the fixation first involves the muscles.

Fixation and dimpling of the skin are not difficult to observe or to elicit. The same is true of retraction of the nipple. Deep fixation is more difficult to ascertain. It is especially difficult

in the many cases in which there is loss of muscle tone due to the degenerative changes of age. Because of this loss of muscle tone the pectoralis major muscle, even with the arm in full abduction, is subject to a wide range of motion, and fixation of the tumor to this structure may not be readily demonstrated by the usual methods. My associates and I have found that fixation can be demonstrated in such cases by an additional maneuver.

After the usual procedures with the arm held at the side and then in abduction in both the sitting and the horizontal position have been carried out, the patient, while in the horizontal position, is requested to bring the arm on the affected side to a right angle and, with the examiner standing in the plane of the axilla on that side, to exert pressure with the arm against the examiner. This procedure actively tenses the pectoralis major muscle so that if the tumor is attached to the pectoralis fascia it will immediately become fixed and immobile.

This maneuver has been used over a period of at least ten years and has been found to reveal fixation of the tumor to the pectoralis major muscle in many cases in which such fixation could not be demonstrated otherwise. I feel, therefore, that it constitutes a valuable additional physical sign of malignant condition of the breast.

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

SHARK LIVER OIL.—The oil extracted from the livers of the shark, mainly of the variety *Hypoprius brevirostris* (lemon), but any or all of the following varieties may be included: *Odontaspis littoralis* (sand), *Isurus punctatus* (mackerel), *Triakis semifasciatus* (leopard), *Sphyrna zygaena* (hammerhead), *Carcharias obscurus* (dusky), *Ginglymostoma cirratum* (nurse), *Carcharias milberti* (white) and *Carcharias limbatus* (black tip). It is biologically assayed to have a potency of not less than 16,500 units of vitamin A (U. S. P.) per gram and of not less than 40 units of vitamin D (U. S. P.) per gram; the latter is insignificant if taken according to directions.

Actions and Uses.—See the general article Fish Liver Oils, Preparations and Concentrates, New and Nonofficial Remedies, 1940, p. 535.

Dosage.—One capsule, or about 8 minims, daily.

Shark liver oil is an amber to brown oily liquid possessing a fishy odor and taste. It is insoluble in water, slightly soluble in alcohol and soluble in chloroform, ether, benzene, ethyl acetate and carbon disulfide. The specific gravity is from 0.917 to 0.923 at 25 C. The refractive index is from 1.475 to 1.480 at 20 C.

A solution of one drop of the oil in 1 cc. of chloroform, when shaken with one drop of sulfuric acid, acquires a light violet color, changing to purple and finally brown or blue. Transfer 5 cc. of oil to a centrifuge tube and add 5 cc. of benzene; centrifugate for twenty-five minutes at 25 C.; no precipitate forms and a clear solution remains.

Fill a tall, cylindrical, standard oil-sample bottle of about 120 cc. capacity with shark liver oil and immerse in a water bath at about 10 C.; the oil becomes turbid at about 15 C. but fluid and clear when the bath is warmed to 45 C.

Transfer 2 Gm. of shark liver oil, accurately weighed, to an Erlenmeyer flask and dissolve in 20 cc. of a mixture of equal volumes of alcohol and ether, which previously has been neutralized with tenth-normal sodium hydroxide, using five drops of phenolphthalein T. S. as indicator, and titrate with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds; not more than 1 cc. of tenth-normal sodium hydroxide is required (*free acid*). The amount of unsaponifiable matter as determined by the method of the U. S. P. XI, page 446, is not less than 3.0 per cent nor more than 6.0 per cent. The saponification value as determined by the method of the U. S. P. XI, p. 445, is not less than 170 nor more than 187. The iodine value as determined by the method of the U. S. P. XI, page 445, on from 0.18 to 0.20 Gm. of sample, accurately weighed, is not less than 125 nor more than 145.

Shark Liver Oil-Shark Industries.—A brand of shark liver oil—N. N. R.

Manufactured by Shark Industries, Inc., Hollywood, Fla. No U. S. patent or trademark.

Capsules Shark Liver Oil, 8.1 minims: Each capsule contains not less than 7,500 U. S. P. units of vitamin A and not less than 18 U. S. P. units of vitamin D.

4. Schiff: Ann. d. Chem., 1859, p. 11289, quoted by Thorpe.³
From the Rees-Stealy Clinic.

DIGILANID.—A mixture of the isomorphous crystallized cardio-active glucosides lanatosid-A ($C_{40}H_{70}O_{16}$), lanatosid-B ($C_{40}H_{70}O_{20}$) and lanatosid-C ($C_{40}H_{70}O_{20}$), obtained from the leaves of *Digitalis lanata*. The three components are present in the mixture in the proportions in which they occur in the crude drug, namely about 47 per cent lanatosid-A, 16 per cent lanatosid-B and 37 per cent lanatosid-C.

Actions and Uses.—The actions and uses are closely similar to those of *digitalis* U. S. P.

Dosage.—The average oral daily dose is from two to four tablets or from 2 to 4 cc. of the liquid until the therapeutic effects are induced or until minor toxic symptoms appear, after which a maintenance dose of about half that just given will usually be sufficient. For rectal administration, one or two suppositories daily. Urgent cases sometimes require the administration of larger oral doses or the intramuscular or intravenous injection of suitable doses. These demand the careful observation of the proper technic, which is described in the circular which accompanies the package.

Manufactured by Sandoz Chemical Works, Inc., New York. U. S. patents 1,923,490 (Feb. 19, 1931; expires 1948) and 1,923,491, (Aug. 22, 1931; expires 1948). U. S. trademark 291,301.

Ampules Digilanid 2 cc. (For Intramuscular Use): Each ampule contains 0.4 mg. of digilanid, equivalent to 1.2 cat units.

Ampules Digilanid 4 cc. (For Intravenous Use): Each ampule contains 0.8 mg. of digilanid, equivalent to 2.4 cat units.

Suppositories Digilanid 0.5 mg.: Each suppository contains 1.5 cat units.

Tablets Digilanid 0.33 mg.: Each tablet contains 1 cat unit.

Vials Digilanid 30 cc.: Each cubic centimeter (16 minims) contains 0.33 mg. of digilanid, equivalent to 1 cat unit.

The dry leaves of *Digitalis lanata* are ground with ammonium sulfate, wetted with water and extracted with ethyl acetate. The filtered extract is evaporated to dryness in vacuo, treated with ether and allowed to stand until the mass becomes solid. The ether is poured off and the residue digested with ether. The dried residue from the operation is pulverized, dissolved in methyl alcohol and treated with lead hydroxide in water. The resultant mixture is neutralized and filtered; the filtrate is concentrated in vacuo and the precipitated glucosidal mixture filtered. The residue is recrystallized from methyl alcohol and water mixtures.

Digilanid crystallizes from aqueous methanol solutions in flat prisms which contain 6 per cent (2 mol.) of methanol and 3.5 per cent (2 mol.) of water as solvents of crystallization. When dried in a high vacuum at 90 C., these solvents are lost. On standing, the dried material takes up approximately 7 per cent of moisture; the dosage of the product is based on this hydrated form.

Air dried digilanid occurs as a white, odorless powder, possessing a bitter taste; soluble in methanol, 1 in 20, very slightly soluble in water, 1 in 10,000, and insoluble in ether. Digilanid, when heated rapidly, melts with decomposition above 245 C.

Transfer 0.002 Gm. of digilanid to a 15 cm. test tube and add 4 cc. of glacial acetic acid and one drop of ferric chloride solution. Add from a pipet 4 cc. of sulfuric acid to underlay the acetic acid solution and allow to stand one hour: a blue color appears in the upper zone (*digitoxose*) and a violet-brown in the lower zone (*mixture of aglucones*). Transfer about 0.02 Gm. of digilanid to a 10 cm. test tube and add 1 cc. each of water, methanol and lead acetate solution: no immediate precipitation or coloration occurs (*appreciable amounts of tannoid substances*). Transfer about 0.02 Gm. of digilanid to a test tube and add 2 cc. of methanol, 2 cc. of water and 0.5 cc. of alkaline cupric tartrate solution, and heat for ten seconds: no turbidity appears (*free reducing sugars*).

Transfer about 0.2 Gm. of digilanid, dried under vacuum and accurately weighed, to a 10 cc. volumetric flask and make up to volume with ethanol. Mix, transfer to a 2 dcm. polarizing tube and observe the angular rotation, using sodium light at 25 C.: the specific rotation $[\alpha]_D^{25}$ is not less than +32.0 and not more than +33.8.

Transfer about 0.2 Gm. of digilanid, dried under vacuum and accurately weighed, to a 150 cc. glass stoppered Erlenmeyer flask and cautiously add 40 cc. of methanol and 20 cc. of tenth-normal sodium hydroxide. Stopper the flask and allow to stand seventy-two hours. To a similar flask add 40 cc. of ethanol and 20 cc. of tenth-normal sodium hydroxide, stopper and allow to stand seventy-two hours. Titrate both solutions with tenth-normal hydrochloric acid, using phenolphthalein as indicator: the volume of tenth-normal sodium hydroxide required by 1 Gm. of digilanid is not less than 20.0 and not more than 23.0 cc.

Transfer about 0.2 Gm. of digilanid, dried under vacuum and accurately weighed, to a 250 cc. separator, add 100 cc. of chloroform, 20 cc. of methanol and 100 cc. of water, and shake at 25 C. for one minute. Separate the layers and evaporate each in vacuo to dryness. Wash the residues into tared weighing bottles with methanol and again evaporate to dryness in vacuo at 55 C., and weigh: the weight of the residue from the chloroform divided by the sum of the weights of the residues is not less than 0.60 and not more than 0.63.

STAPHYLOCOCCUS ANTITOXIN.—Antitoxin prepared by immunizing horses with staphylococcus toxoid and/or staphylococcus toxin.

Actions and Uses.—Staphylococcus antitoxin is suggested in the treatment of acute and severe staphylococcal infections with or without septicemia. Its use in treatment calls for adequate dosage administered early; most of the antitoxin estimated to be necessary for the entire treatment of the infection should be injected during the first few hours after decision is made to use the serum. Supplementing the use of antitoxin in the more severe types of staphylococcal infections, surgical drainage of accessible foci and transfusions with normal or immune donors should be a part of the treatment.

Dosage.—For the treatment of localized infections, 10,000 units. For the treatment of more severe infections, from 30,000 to 100,000 units early during the first day in divided doses, followed by from 20,000 to 100,000 units daily until the pulse rate and temperature have subsided and the blood cultures are sterile for three consecutive days.

Lederle Laboratories, Inc., Pearl River, N. Y.

Staphylococcus Antitoxin "Globulin-Lederle-Modified."—An antitoxic serum prepared by immunizing horses with gradually increasing doses of staphylococcus toxoid and/or staphylococcus toxin. The serum is refined by a controlled method of selective digestion of the proteins of the immune horse blood with pepsin which digests up to 90 per cent of the coagulable protein; a smaller portion is precipitated and the remainder, a pseudoglobulin fraction, is purified first by ordinary filtration and then by ultrafiltration and dialysis. The serum is standardized on the basis of the international unit which was adopted by the Permanent Commission on Biological Standardization of the Health Organization of the League of Nations in August 1934, the unit being equivalent to approximately 125 original antidermonecrotic units, an antidermonecrotic unit being that amount of antitoxin required to neutralize one necrotizing dose of staphylococcus toxin. Marketed in packages of one vial containing 10,000 international units and in packages of one vial containing 20,000 international units.

CROTALUS. ANTITOXIN (See New and Nonofficial Remedies, 1940, p. 419).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

"Lyovac" Antivenin (Nearctic Crotalidae) Polyvalent.—North American Anti-Snake-Bite Serum.—A lyophilized antitoxic serum prepared by injecting horses with venoms from serpents of the North American species of the family Crotalidae (rattle-snake venoms, 90 per cent; moccasin venoms, 10 per cent. Moccasin venoms include both the cotton-mouth moccasin and the upland moccasin or copperhead). The bulk globulin before lyophilization is tested for sterility. The following safety test is made: 3 cc. of the finished antivenin is injected into each of two guinea pigs. Both animals must remain healthy for at least seven days. The total solids content must not exceed 20 per cent. The product is standardized for potency so that 1 cc. of the antivenin will neutralize 20 minimum lethal doses of venom injected intravenously into 350 Gm. pigeons. With standard rattlesnake venom (*Crotalus atrox*), the amount neutralized by 1 cc. of antivenin equals 3 mg. of the dried venom.

The process of lyophilization consists in the following: The antivenin in specially designed final containers is rapidly frozen by immersion in a freezing mixture to convert the substance with the least molecular rearrangement. The container is then subjected to a high vacuum to accomplish dehydration, which is continued until the residual moisture content is less than 1 per cent.

Marketed in packages of one ampule-vial containing a sufficient amount of lyophilized antivenin to yield 10 cc. of refined and concentrated globulin with one syringe containing 10 cc. of distilled water (preserved with phenol 0.35 per cent) and a 1 cc. ampule-vial of normal horse serum (diluted 1:10) as test and desensitizing material.

IMMUNE GLOBULIN (HUMAN) (See New and Nonofficial Remedies, 1940, p. 437).

The Gilliland Laboratories, Inc., Marietta, Pa.

Immune Globulin (Human).—Human placentas from healthy mothers are extracted in sodium chloride solution. After extraction the centrifuged supernatant is refined and concentrated with ammonium sulfate in a manner similar to that used for diphtheria antitoxin. The resulting concentrate is dialyzed to remove sulfates and is preserved with 0.1 per cent of phenol and 0.01 per cent of sodium ethyl-mercuri-thiosalicylate and passed through a bacteriologic filter. The product is standardized by assay in guinea pigs of the diphtheria antitoxin content. Marketed in packages of 2 cc. and 10 cc. vials.

SULFANILAMIDE (See New and Nonofficial Remedies, 1940, p. 489).

The following dosage form has been accepted:

Sulfanilamide Tablets, 7½ grains.

Prepared by Sharp & Dohme, Philadelphia and Baltimore. No U. S. patent or trademark.

ANTIPNEUMOCOCCUS SERUM TYPES I AND II COMBINED (See New and Nonofficial Remedies, 1940, p. 432).

Mulford Biological Laboratories, Sharp & Dohme, Inc., Philadelphia and Baltimore.

Antipneumococcus Serum, Concentrated (Pneumococcus Antibody Globulin, Types I and II).—(See New and Nonofficial Remedies, 1940, p. 433). Also marketed in packages of one ampule vial containing 20,000 units each of types I and II, and in packages of one ampule vial containing 50,000 units each of types I and II.

***CAFFEINE WITH SODIUM BENZOATE** (See New and Nonofficial Remedies, 1940, p. 168).

The following dosage form has been accepted:

Endo Products, Inc., Richmond Hill, New York.

Ampoules Caffeine with Sodium Benzoate, 2 cc.: An aqueous solution containing in each 2 cc. caffeine with sodium benzoate-U. S. P. 0.5 Gm. (7½ grains).

SULFAPYRIDINE (See New and Nonofficial Remedies, 1940, p. 494).

Sulfapyridine-Wyeth.—A brand of sulfapyridine-N. N. R.

Manufactured by John Wyeth & Brother, Inc., Philadelphia. No U. S. patent or trademark.

Tablets Sulfapyridine-Wyeth, 0.5 Gm. (7.7 grains).

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

Data pertaining to the major activities of the Council are presented annually in the Educational Number of *THE JOURNAL*. In the following pages will be found the usual report on preliminary and undergraduate medical education with a description of the approved medical schools and revised lists of hospitals approved for the training of interns and approved for residencies and fellowships in the specialties. A summary of the activities of the various agencies interested in continuation courses for practicing physicians is here given, as well as the Principles Regarding Graduate Medical Schools ratified by the House of Delegates of the American Medical Association at its recent New York session. Finally there are included the official requirements of each of the fifteen approved examining boards in medical specialties.

This issue of *THE JOURNAL* constitutes a valuable source of information for students, interns, residents and practicing physicians as well as those interested in specialty certification. It may equally interest deans and other officials of medical schools, licensing agencies, the directors and staffs of hospitals, and the various general and special societies interested in the promotion of graduate and postgraduate medical education.

These data are based on official reports. The Council and *THE JOURNAL* express thanks and appreciation to the officials of the institutions and agencies named and to others for their cordial cooperation in supplying the material submitted in this presentation and for other records furnished throughout the year to the office of the Council and the members of its staff on inspection or visitation, enabling the Council to maintain its medical student and hospital registers efficiently and to carry on its activities as outlined by the House of Delegates of the American Medical Association.

PRELIMINARY EDUCATION

The Council's minimum requirement for admission to approved medical schools is two years of college training which include English, and theoretical and

practical courses in physics, biology and general and organic chemistry. Three years or more in college is, however, recommended. Since it cannot be generally assumed that all who have satisfied these requirements in terms of hourly credits are fitted for the study of medicine, qualitative standards also are imposed.

As a rule applicants receive their preliminary education in institutions approved by accrediting agencies. Exception may be made in the case of those who demonstrate superior ability. For the convenience of students and admitting officers the Council publishes

TABLE 1.—Requirements for Admission to Medical
Schools, 1936-1940

	Degree	Years				
		Four	Three*	Three	Two and One-Half	Two

Statistics of Recognized Schools of the Basic Medical Sciences will be found in table 3, page 688.

* On probation since Dec. 4, 1933.

** Enrolment not on above table by classes for the two medical schools of the University of Chicago.

† Fifth year (internship) enrolment not included in the total column.

‡ Fifth year discontinued beginning with the class of 1940.

H Two year Internship required after graduation; 1st year, 61; 2d year, 54.

I Sixth year enrolment; Alberta, 36; Queen's, 58; Western Ontario, 29; Toronto, 132.

J Fifth year discontinued beginning with the class of 1940; one year Internship required to be eligible for licensing examinations.

† Students admitted at different times of the year: Colorado, advanced students beginning of 2d or 3d quarters; Northwestern, beginning of any quarter; University of Chicago, spring and summer quarters; Minnesota, winter quarter (freshmen only); Tennessee, Sept. 23, Dec. 30, 1936, and March 26, 1941.

(Continued from page 685)

itself recommends three years of college preliminary to entrance into medical school and because all but a negligible percentage of medical students have actually taken three years or more in college. Under these conditions the medical schools are selecting their students from among those candidates who are already enrolled in colleges of arts and sciences which offer the full four year course leading to a bachelors' degree. One hundred and thirty-three junior colleges were included in the last published list.

There are 671 colleges of arts and sciences, exclusive of junior colleges, approved by the standardizing agencies, distributed as follows:

Association of American Universities.....	291
North Central	249
Southern	180
Middle States	124
Northwest	57
New England	44

Of those recognized by the Association of American Universities, all but seventeen are approved also by

the end of the first year in medicine, three years, two and one-half years and two years. The nine schools which have a stated two year requirement for the session 1940-1941 are the Universities of Arkansas, Medical Evangelists, George Washington, Howard, Louisville, Harvard, Buffalo, Pittsburgh and Tennessee. Creighton University School of Medicine and Meharry Medical College have increased their prerequisite for the forthcoming session to three years.

The general trend toward three or more years of college work would appear to be due to a desire for more thorough grounding in all the branches of chemistry and greater familiarity with nonscience subjects, such as literature, history or economics. In table 4 it will be noted that actually only 2 per cent of the entire freshman class of 1939-1940 were admitted with less than three years. Of the eleven schools with a two year requirement, two admitted none on this basis, two admitted one each, two admitted three each and one accepted nine students. One hundred entered four schools, although in each case they represent less

their district agency. In the various groups this dual approval of 274 institutions is apportioned as follows:

North Central	103
Southern	59
Middle states	63
New England	31
Northwest	18

The five regional associations of colleges referred to cover among them the entire United States with the exception of the far Southwest. Institutions in this area can secure only the approval of the national group—the Association of American Universities.

For the session 1939-1940, sixty-six of the seventy-seven medical schools in the United States had a premedical prerequisite in excess of the minimum. For 1940-1941 only nine schools will admit students with less than three years of preparation. In table 1 are tabulated for five sessions the figures indicating the trend toward increasing admission requirements with the number of schools requiring a degree, four years, three years if the baccalaureate degree is conferred in absentia at

than 50 per cent of the freshman class. In 1936-1937, 12.5 per cent of the entering class had only the minimum of preliminary education, but by 1938-1939 the number had dropped to 3.8 per cent and in 1939-1940 to 2.0 per cent.

The faculties of medicine in Canada vary in their premedical requirement. For the session 1940-1941 two require a degree for admission to a five year course; four have a six year medical course preceded by senior matriculation which is equivalent to the work of the first year in a college of arts and three, including one school offering courses in the basic sciences, require two years, and one school requires three years before beginning a four year course. A table appears later in this study which records the number of graduates of 1940 holding baccalaureate degrees (table 18).

With but five exceptions, namely California, Connecticut, Massachusetts, Missouri and Nebraska, the state licensing boards require two years of preliminary college training. The law in Massachusetts will change

in 1941. Although their statutes do not include the two year college requirement, these states with the exception of Massachusetts do not license other than graduates of approved schools. Alaska, Hawaii and Puerto Rico likewise require two years of preliminary training. The requirement of the medical licensing board of each state is shown in table 5.

DURATION OF MEDICAL COURSE

The medical course in the United States in general is taught in four years of approximately thirty-two weeks each. Fifty-two offer such a course. The medical schools of the Universities of Northwestern, Minnesota, Duke and Tennessee operate on the quarter system, permitting a student by utilizing the summer months to decrease the length of time necessary to obtain a degree. A considerable number of the students of these schools do not elect to study during the summer months. The medical schools of the University of Chicago are operated on a plan of individual promotion permitting a student to advance as rapidly as he desires, but the great majority complete the course in twelve quarters. Medical practice acts of certain states, however, specify a four year professional course and it is advisable that students should assure themselves concerning the legal interpretation of the phrase.

Fifty-six schools require a four year course, while eleven, including those operated on the quarter plan, require four years of systematic instruction followed by a fifth year spent as an intern or in research work.

Ten schools in the United States and one in Canada offer only the first two years of the medical curriculum and are designated as schools of the basic medical sciences. For the most part these schools are located in smaller communities where the clinical material required for teaching is almost wholly lacking. In some instances, facilities for the satisfactory teaching of such subjects as physical diagnosis and gross pathology must be sought at a distance from the school. Introductory courses in medicine and surgery, which commonly form a part of the second year schedule, may be similarly handicapped. A study of the problem led to the adoption in February 1937 of this policy, which became effective July 1, 1939. For these reasons the Council

TABLE 4.—First Year Students Admitted with Less than Three Years of College Preparation

	Number of Schools With Two Year Requirement	Percentage of Students
1936-1937.....	32	12.5
1937-1938.....	37	7.4
1938-1939.....	19	3.5
1939-1940.....	11	2.0

in giving its approval to schools of the basic medical sciences assumes no responsibility for the character of those courses which involve the use of clinical material.

Four of the medical schools of Canada offer a five year course, four have a six year course, one offers four years and there is one school of the basic sciences, referred to in the preceding paragraph. Three Canadian schools require an internship for graduation.

These data are shown in tables 2 and 3, listing separately:

1. Recognized medical schools in the United States and Canada.
2. Recognized schools of the basic medical sciences in the United States and Canada.

In subsequent tabulations the figures for the two groups are combined in an effort to present the picture of medical education as a whole.

MEDICAL SCHOOL SURVEY

During the academic years 1934-1936 a resurvey of all medical schools in the United States and Canada was made by the Council. Dr. Herman G. Weiskotten,

TABLE 5.—Preliminary Training Required by Licensing Boards

dean of Syracuse University College of Medicine, visited all schools in company with a representative of the Council, the Association of American Medical Colleges or the Federation of State Medical Boards. Three days was customarily spent at each school. Some time before each school was visited, a set of questionnaires was sent including reports by the dean on the organization and administration of the school, the clinical facilities and hospital relationships, and each department in the school, including the library. These questionnaires called for information on departmental organization, staff, facilities, hours in the medical curriculum, methods of conducting courses, research, relationship with other departments, and budget. There was also provided a separate personal history form for every member of the faculty holding the rank of assistant professor and above. This called for an outline of training and experience, scientific society memberships, participation in scientific programs, publications, proportion of time devoted to teaching and research, and participation in community programs related to the field of medicine. The questionnaires were usually not examined before a school was visited, thus enabling those visiting the school to get a more objective picture. However, all questionnaires were carefully studied before an evaluation was made. Careful notes were kept of the inspections. All data dealing with the survey, including the questionnaires, notes on the visits, laboratory outlines, literature dealing with the conduct of courses, published reports and catalogues are filed in the office of the Council.

To all schools there was sent a confidential report in graphic form, referred to as a pattern map. This method, which had already proved its usefulness to the North Central Association of Colleges and Secondary Schools, was adapted by the Council to suit its own needs. The sixty-six four year medical schools in the United States, arranged in rank order with

(Continued on page 692)

of Students

[illegible]

(Continued from page 689)

respect to ninety-six items, served as the basis of these charts. For the schools offering instruction only in the basic sciences and for the medical schools of Canada, similar graphs were prepared, each school being placed in the same decile rank as other schools with approximately the same evaluation.

A committee of the Council consisting of Dr. Weiskotten, Alphonse M. Schwitalla, S.J., Ph.D., Dean, St. Louis University School of Medicine, William D. Cutter, M.D., Secretary, and Hamilton H. Anderson, M.D., a member of the staff, Council on Medical Education and Hospitals, prepared a final report which was released in January 1940. This publication is entitled "Medical Education in the United States, 1934-1939,"¹ Without naming individual schools, the report describes in general terms the organization and administration, the faculty and student personnel, and the clinical and financial resources of the medical schools, thus presenting an objective picture of medical education in this country for the years under review. In this way it was believed that faculties and administrative officers may learn what other schools are doing, emulating that which is good and avoiding that which experience has shown to be unprofitable.

DEVELOPMENTS IN MEDICAL EDUCATION

Reports received from a large number of medical schools and follow-up inspections of many indicate that, as a result of the Council's survey, substantial improvements have been and are being made. Where facilities were inadequate the size of classes has been reduced, entrance requirements have been raised, the teacher-student ratio in the basic medical science departments in 1939 was 1:8 as compared to 1:11 in 1934, clinical facilities have been improved, budgets have increased and curriculums have been revised.

In summary the report¹ declares that "Some of the most important changes and significant improvements of recent years do not lend themselves to statistical treatment. Imponderables still count heavily. In some institutions administrative reorganizations have greatly strengthened personnel and educational programs. In such efforts the Council has cooperated and in some instances has aided substantially in securing for the schools from trustees or legislative bodies greater financial and administrative support. The procedure of the Council has been different from what it was in 1905-1910 for the reason that the whole picture of medical education is radically different from what it was thirty years ago. Even the weakest of the medical schools at the time of this survey was a stable institution as compared with the numerous proprietary schools and diploma mills in existence at the time that the Council was created. Rather than to publicly proclaim their deficiencies, therefore, it seemed wiser to give aid and encouragement to those schools which needed help, in the hope that within a reasonable period they would be able to conform to the current standards of medical education. This expectation has been justified by the achievements of the past three or four years during which the Council has been able to stimulate greater interest in medical schools on the part of their universities; to assist administrative officers in the solution of their problems of organization and personnel; to assist in securing satisfactory hospital relationships; to foster the development of more modern educational programs

and stimulate curricular studies by faculty groups, and to secure greater financial and public support. In all of these ways and many others the cause of medical education has been promoted, its standards advanced and its purposes more nearly achieved."

Since the Council's first classification of medical schools and the publication of the Carnegie report,² there has been probably no five year period which has witnessed such activity and progress in the field of medical education.

CURRICULUM

The standard curriculum recognized by the Council on Medical Education and Hospitals and contained in its Essentials of an Acceptable Medical School consists of from 3,600 to 4,400 distributed as from 900 to 1,000 hours a year and grouped under nine headings: anatomy, including histology and embryology; physiology; biochemistry; pathology, bacteriology and immunology; pharmacology; hygiene and sanitation; general medicine; general surgery, and obstetrics and gynecology. A certain percentage of hours of the whole number of hours in the courses is required in each of these groups.

APPROVAL OF SCHOOLS IN CANADA

On June 24, 1937, at a meeting in Ottawa, Ont., Canada, at which representatives of the medical schools in Canada and the assistant secretary of the Canadian Medical Association were present, the secretary speaking for the Council on Medical Education and Hospitals discussed the survey of Canadian medical schools made during 1934-1936 and inquired as to the policy to be adopted in the future—that is, whether the American Medical Association should continue the grading of medical schools in Canada or whether they would prefer that the medical schools themselves or some other body take over this task. The problem was referred to the Canadian Medical Association.

At its sixty-ninth annual meeting in June 1938 the Committee on Medical Education of the Canadian Medical Association brought in a report which was accepted by the members of the General Council of the Canadian Medical Association and reads, in part, as follows:

"In the event of the Council on Medical Education of the American Medical Association publishing a list of approved schools, those Canadian schools wishing their inspection and approval could request this inspection. This would leave each school free to deal directly with the Council on Medical Education of the American Medical Association and thus obviate misunderstandings.

"There seems to be a fairly uniform opinion expressed by the various medical schools in Canada that the Canadian Medical Association should share some responsibility in this country so far as medical education is concerned. The majority of the schools, however, feel that the aims and purposes of the Canadian Medical Association are not primarily those of undergraduate medical education, which is largely a problem of the schools themselves. However, it was recommended that, if the Council on Medical Education and Hospitals of the American Medical Association in the future conduct similar surveys at five or ten year intervals, such as the recent survey, the Canadian schools take advantage of and be included in this survey. Those schools which are members of the Association of American Medical Colleges could have a representative from

1. Weiskotten, H. G.; Schwitalla, A. M.; Cutter, W. D., and Anderson, H. H.: *Medical Education in the United States*, Chicago, American Medical Association, 1940.

2. *Medical Education in the United States and Canada*, Carnegie Foundation for the Advancement of Teaching, 1910.

this association included in the personnel of the inspection. The remaining schools which are not members of the Association of American Medical Colleges could ask to have a member of the Association of American Medical Colleges included in the inspecting personnel, or some representative from the Committee on Medical Education of the Canadian Medical Association."

It would appear from the foregoing that the approval of Canadian medical schools by the Council on Medical Education and Hospitals of the American Medical Association rests with the schools themselves.

The Council on Medical Education and Hospitals at a meeting in St. Louis on May 13, 1939, voted that after Jan. 1, 1945, the Canadian medical schools will be included in the Council's classification only at their own request.

STATISTICS OF MEDICAL SCHOOLS AND SCHOOLS OF THE BASIC MEDICAL SCIENCES

Medical schools and schools of the basic medical sciences approved by the Council on Medical Education and Hospitals during 1939-1940 are listed in tables 2 and 3, pages 686 and 688. Recorded therein is the preliminary requirement for the session 1940-1941 by years, the length of the medical course by years, enrolment by classes for the session 1939-1940, including fifth year students interning or engaged in research, total attendance, the number of graduates since July 1, 1939, the dates of the beginning and ending of the forthcoming session, the month until which applications for admission to the freshman class are received and the name of the dean or executive officer. Three schools on probation are indicated by an asterisk preceding the name. There have been no changes in the classification of any medical school since the publication of the educational statistics in 1939. Also contained in the footnotes are references to the fifth and sixth year enrolments and names of the schools which admit students at varying times during the year. The fifth year (internship) enrolment is not included in the column giving the total number of students by classes. At Louisiana State University Medical Center the fifth or intern year was discontinued beginning with the class of 1940 but there were sixty-four students who completed the four year course in 1939 and were awarded degrees in 1940 on completion of the internship, but seventy-two students who completed four years in 1940 were awarded degrees without serving an internship. Duke University School of Medicine requires a two year internship after graduation. The number in hospitals during this period are also included in a footnote. The two medical schools of the University of Chicago do not report their students by classes, and in this tabulation therefore only the total enrolment is given. The fifth, or intern, year was also discontinued by McGill University Faculty of Medicine with the class of 1940, but the school will maintain a record of those who intern, since it is a requirement for medical licensure.

Similar data pertaining to the schools of the basic medical sciences are given in table 3. The data presented in tables 2 and 3 constitute the basis also for several of the subsequent tabulations, and beginning on page 701 are given historical information and essential facts concerning the schools arranged by states.

Sixty-seven medical schools in the United States and nine faculties of medicine of Canada are listed; also ten schools of the basic medical sciences in the United States and one in Canada. All but three of these schools at the present time enjoy the approval of the

Council, the three being on probation. In eighty-five schools 6,445 freshmen students were enrolled, 5,735 sophomores, 5,447 juniors, 5,439 seniors, 388 fifth year and 255 sixth year students during the session just ended. In the two medical schools of the University of Chicago 485 students were enrolled, making a total of 24,194 in the eighty-seven schools listed. In the United States there were 5,794 freshmen, 5,177 sophomores, 4,921 juniors, 4,894 seniors and the 485 students of the University of Chicago, a total of 21,271. The total number of students in the United States registered by classes, including fifth or intern year students, was 22,423. The enrolment in the schools of the basic medical sciences in the United States numbered 603, of which 318 were freshmen and 285 sophomores. The enrolment in the ten Canadian schools was first year 651, second year 558, third years 526, fourth year 545, fifth year 388 and sixth year 255, a total of 2,923. In the one school of the basic medical sciences in Canada there were forty-eight students: twenty-four freshmen and twenty-four sophomores.

Medical students enrolled in institutions in the United States and Canada numbered 24,194, exclusive of 1,152 fifth year students in the United States interning or engaged in research and 132 in Canada interning as a requirement for the degree of Doctor of Medicine or in order to be eligible for licensure.

Since July 1, 1939, 5,703 received the degree of Doctor of Medicine, 5,097 from schools in the United States and 606 from Canadian institutions.

There were also 108 part time, 228 special and 606 physicians or graduate students studying in medical schools.

With one exception the schools of the basic medical sciences had an enrolment of considerably less than 100. The lowest enrolment among the regular medical schools was 103 students at the Woman's Medical College of Pennsylvania and the highest 777 at the University of Toronto Faculty of Medicine. The correspondingly high figure among schools in the United States was 636 enrolled at the University of Illinois College of Medicine.

Eleven schools, exclusive of those of the basic medical sciences, matriculated 200 or less, thirty-two between 201 and 300, sixteen from 301 to 400, twelve from 401 to 500, and three from 501 to 600. Two schools matriculated more than 600. The smallest enrolment (forty-two) was at Dartmouth Medical School, where twenty freshmen and twenty-two sophomores were enrolled. This school does not offer the complete medical course.

The Woman's Medical College likewise graduated the lowest number, eighteen. The school granting degrees to the greatest number was the University of Illinois College of Medicine, which awarded 162 diplomas. Twenty-three schools granted degrees to classes of fewer than fifty students, thirty-three schools graduated between fifty-one and 100 each, seventeen from 101 to 150 and three less than 200 but more than 150.

The majority of schools will begin the session 1940-1941 about the middle of September and complete the year's work early in June.

Seventy schools replied to the inquiry regarding the month until which applications for admission to the first year class will be received. Seventeen replied March, sixteen September, seven each June and August, six each April and May, five February and three each January and July.

In reply to the question "Is a deposit required with application?" fifty-eight schools reported "no" while twenty-seven gave an affirmative answer. Of the latter, eight indicated the fee was returnable and nineteen that it was not. Fifteen required with the application a deposit of \$5 or less and twelve reported from \$10 to \$100, i. e. one reports \$10, two \$20, four \$25, four \$50 and one \$85, while three of these schools had a nonresident fee of \$25, \$50 and \$100 respectively. Of those requiring a deposit of \$20 or more, four indicated that the fee was not returnable and made no comment, one stated that it was not returnable if the student accepts an appointment in another medical school, and another stated it was returnable if notice of withdrawal

is given in time to permit the vacancy to be filled. Four schools stated that an acceptance fee of \$50 was required.

BIRTH PLACE OF STUDENTS

The birth state of students in attendance in medical schools during 1939-1940 is shown in table 6, pages 690 to 691. The greatest number of students registered, 2,766, according to state of birth, was from New York, followed by Pennsylvania with 1,867, Illinois with 1,356 and Ohio with 1,068. From each of four states there was a student enrolment of between 701 and 1,000 and between 501 and 700, from three states 401 to 500, from seven states between 301 and 400, from ten states 201 to 300, from eleven states, 101 to 200, and from six states less than 100.

There were 196 born in the United States territories and possessions studying in forty-six schools in the United States and three in Canada. In addition, 2,577 students of Canadian birth were also studying medicine, 128 of whom were matriculated in forty-four schools in the United States and 2,449 in the ten Canadian medical schools. Fourteen students of Canadian birth were registered at the College of Medical Evangelists,

thirteen at Wayne University College of Medicine and nine at the University of Oregon Medical School. Other schools registered less than seven. Students born in New York were enrolled in all but four states, namely North Dakota, South Dakota, Utah and West Virginia. Students from New York were registered in four of the six provinces of Canada having medical schools. None were studying in Alberta or Saskatchewan. Pennsylvania was represented in all but six states and three provinces.

There were 742 students from New Jersey, which has no medical school, admitted to sixty-two schools, while 292 from the state of Washington were enrolled in fifty-one schools.

Foreign born students were matriculated in sixty-eight of the seventy-seven medical schools in the United States. There were 511 so enrolled, of whom thirty-two each were studying at the College of Medical Evangelists and the University of Illinois College of Medicine, twenty-five at New York University College of Medicine and twenty-four at Harvard Medical School. Other schools registered fewer than sixteen. It may be presumed that many of these are now citizens of the United States.

From the twelve states in which no medical schools are located there were 1,860 students in at least sixty-two schools as follows:

	Enrolled	No. of Schools
Arizona.....	53	32
Delaware.....	36	16
Florida.....	180	39
Idaho.....	102	32
Maine.....	113	31

New Mexico.....	43	27
Rhode Island.....	110	25
Washington.....	292	51
Wyoming.....	33	19
Totals.....	1,860	

The classification of students by birthplace is extended further in table 7 for the medical schools of the United States and Canada. This compilation reveals that 13,585 students are studying in the state of their birth and 10,609 elsewhere. In the schools of Illinois 953 were born in the state and 1,026 elsewhere. More than 900 born outside the state were enrolled in institutions in New York and Pennsylvania but the number of those born within and studying in these states was greater. Schools located in California, Connecticut, the District of Columbia, Kentucky, Louisiana, Maryland, Massachusetts, Missouri and Tennessee enrolled more students born outside the state than from within.

In the United States 11,136 students were attending school in the state of their birth and 10,135, or 44 per cent, elsewhere. Eliminating the 1,860 from states which have no medical school, there are still 8,749 of the total number of students, 24,194, studying outside their birth state. Similar figures for Canada are, respectively, 2,449 and 474.

RESIDENT AND NONRESIDENT STUDENTS

Data regarding students classified as residents or nonresidents are enumerated in table 8. Among state universities, as well as other schools, there is a wide variation in the definition of the term "resident." In some universities this is determined by the legal or permanent residence of the student, parents or guardian

only, while in some schools continuous residence for from six months to one, two or three years just prior to the student's application for enrolment is also required. Others require the student to be a voter; that the parents' home in the state be established prior to

the beginning of premedical work; the student to be a taxpayer or a dependent of a taxpayer, regardless of whether he resides in the state, or require the student to be self supporting. In some schools each case is determined by an attorney after consideration of birth, citizenship, residence of parents, and so on. The most common method is the determination of residence by ascertaining whether the student, parents or guardian has been a bona fide resident for a period of not less

than six months. In some schools also a student coming into the state for educational purposes only would not be considered a resident. Among medical schools not a part of a state university the term "resident" is defined mostly by the home address of the student or the legal residence of the parents or guardian. In one school a student is considered a resident if he lives in the state.

On the basis of these factors, in the sixty-seven approved medical schools and the ten approved schools of the basic medical sciences in the United States there were 13,292 students reported as residents and 7,979 as nonresidents. The state university enrolling the greatest number of nonresidents was the University of Tennessee College of Medicine, which had 233 residents and 206 nonresidents, while at the Universities of Georgia, Missouri, Ohio State, Texas and West Virginia nonresidents were not registered and only one of the 636 students of the University of Illinois College of Medicine was a nonresident.

Among other than state universities, it is of interest to note the resident and nonresident enrolment. Many of the schools select their students from among residents of the state. This is particularly significant at the Universities of Southern California, Stanford, Tufts, Long Island, Buffalo and Syracuse. The enrolment in municipal medical schools consisted largely of resident students.

TABLE 9.—*Resident and Nonresident Students, 1936-1939*

	Resident	Nonresident	Totals
1936-1937.....	14,026	8,069	22,095
1937-1938.....	13,518	8,069	21,587
1938-1939.....	13,418	7,884	21,302
1939-1940.....	13,292	7,979	21,271

The figures in tables 7 and 8 giving the number of residents and nonresidents and the preceding one classifying students by birthplace show a divergence. More than 2,000 students born outside the state have been classed as residents. Excluding Canadian registration given in table 7 there were 11,136 attending school in the state of their birth and 10,135 elsewhere, as compared with 13,292 whose legal residence is in the state in which they are pursuing their medical courses and 7,979 classified as nonresidents.

The study of resident students has been carried on for four years. For purposes of comparison the figures for the sessions 1936-1939 inclusive are reproduced in table 9. As will be noted, the figures do not vary to any measurable extent.

The ten faculties of medicine of Canada, including one offering courses in the basic medical sciences, reported 2,120 residents of Canada and 803 nonresidents. The definition of a resident by these schools varied from students whose permanent address is within one of the provinces of Canada, or the specific province in which the school is located, to home address on registration and taxpayers. The greatest number of nonresidents in any one school was reported by McGill University Faculty of Medicine, where 277 of the 444 students enrolled were nonresidents. This school obtains a large portion of its student body from the United States. Dalhousie University Faculty of Medicine registered the second greatest number of nonresidents, seventy-eight of an enrolment of 183. All other schools enrolled fewer than sixty-one with one exception—the University of Toronto Faculty of Medicine, where 195 of an enrolment of 777 were nonresidents.

Comparing the figures for Canada in table 7, as in the United States, reveals somewhat similar figures: 2,449 born in Canada and 474 elsewhere, compared with 2,120 residents and 803 nonresidents.

SCHOOLS, STUDENTS AND GRADUATES BY STATES

Medical schools are located in thirty-six states and the District of Columbia. In table 10 are tabulated the

* Excluding fifth or intern year students.

number of schools, students and graduates by states. Nine schools are located in the state of New York and this state naturally had the greatest number of students and graduates, 2,589 and 597 respectively. Pennsylvania with six schools had 2,337 students and 569 graduates; Illinois with five schools 1,979 students and 574 graduates ranks third, while Massachusetts with three schools, 1,113 students and 282 graduates completes the group of states having an enrolment of more than 1,000, although California had 999 students and 259 graduates.

In the seventy-seven schools, including those that offer courses in the basic medical sciences only, there were 21,271 students and 5,097 graduates. Students intern- ing as a requirement for the degree, or fifth year students, are not included in this tabulation. Neither are part-time, special and graduate students. The greatest number of graduates in any one state was 597 who completed their courses in New York schools. There were 574 from Illinois schools and 569 from schools in Pennsylvania. Five other states had more than 200 graduates—California, Louisiana, Massachusetts, Missouri and Ohio. Ten states had more than 100 but less than 200 graduates. Seven states had no graduates, as the medical schools located therein do not offer the complete medical course. All others had less than 100.

The status of two medical schools will change in the future:

Undergraduate courses at Rush Medical College will terminate in June 1942, when the students now enrolled

will complete their studies. All undergraduate instruction will thereafter be given on the University of Chicago campus and Rush will become a postgraduate school. The college is now designated The Rush Graduate School of Medicine. Graduate courses are being organized. Wilber E. Post, M.D., has been appointed dean of the graduate school.

On Aug. 4, 1939, the Board of Trustees of Wake Forest College accepted the resources of the Bowman Gray Foundation in Winston-Salem and authorized the medical school to be moved to that city and expanded to offer instruction to include the entire four years leading to the M.D. degree. The physical plant is now under construction. The date of the beginning of the clinical years has not been announced.

REQUIRED INTERNSHIPS

The medical schools and licensing boards requiring a hospital internship for the M.D. degree and state licensure, respectively, are shown in tables 11 and 12. Twelve schools in the United States and three in Canada require an internship for graduation. Several medical schools accept research or other clinical work in lieu of hospital service. The University of Minnesota in 1915 was the first school to adopt this basis for its degree. The two medical schools of the University of Chicago, i. e. Rush Medical College, which had required the internship for the M.D. degree since 1919, and The School of Medicine since 1930, discontinued this formal requirement in 1936. Louisiana State University Medical Center, which since the medical school

was organized in 1931 has offered a five year course including an internship, discontinued the hospital year beginning with the class of 1940. The fifth year was also discontinued by McGill University Faculty of Medicine as a result of the reorganization of its medical curriculum affecting the freshman class of 1936-1937. The M.D. degree is conferred on completion of four sessions of thirty-six teaching weeks but the holders

of these degrees are not eligible to sit for the licensing examination until the completion of a hospital internship. The M.D. degree is likewise conferred by Duke University School of Medicine after completion of the senior year, but all graduates are required to spend at least two years in a hospital or in laboratory work after graduation.

The medical licensing boards of twenty-two states, the District of Columbia, Alaska, Hawaii and Puerto Rico require that all candidates for licensure possess a hospital internship. The first state to adopt this requirement was Pennsylvania in 1914. In addition, other states exact the internship of graduates of faculties of medicine abroad and of applicants for reciprocity or endorsement.

Some of the medical schools and licensing boards have their own list of hospitals acceptable for intern training but the Council's approved list is generally in use. A revised edition will be found beginning on page 752.

There were 1,152 students in the United States and 132 in Canada reported as completing the fifth or intern year requirement of the medical schools which exact the fulfilment of the internship as requisite for the M.D. degree. In addition, statistics computed indicate that 98 per cent of the graduates of recent years have obtained or are obtaining this added experience.

DISTRIBUTION BY SEX

Students and graduates in the United States and Canada classified according to sex are shown in table 13. Seventy-six schools had both men and women students, of which fifty-nine had women graduates. Of

TABLE 14.—Distribution by Sex in the United States and Canada, 1936-1939

Year	Students		Graduates	
	Male	Female	Male	Female
1935-1936.....	24,219	1,254	5,388	268
1936-1937.....	23,787	1,244	5,624	261
1937-1938.....	23,234	1,307	5,439	252
1938-1939.....	22,919	1,293	5,290	285
1939-1940.....	22,903	1,291	5,430	273

this total, nine Canadian faculties had students of both sexes and four had women graduates as well as men. Women were enrolled in seven of the ten schools in the United States offering courses of the basic medical sciences and also in the one such school located in Canada. Altogether there were 22,903 men and 1,291 women students and 5,430 men and 273 women graduates. Of these, 20,126 male students and 4,844 graduates were in schools in the United States and 2,777 and 586 respectively in Canada. Likewise there were 1,145 female students and 253 graduates in the United States and 146 students and twenty graduates in Canada. Of the male students and graduates, 2,661 and 892 respectively were enrolled in schools in the United States which are not coeducational and 278 and 227 in Canada.

An average of seventeen women students were enrolled in the sixty-seven coeducational institutions in the United States and three graduates from fifty-five schools.

Figures are given in table 14 showing this distribution for a five year period.

WOMEN IN MEDICINE

Elizabeth Blackwell was graduated in 1849 from the Geneva Medical College of Syracuse, N. Y., now known as Syracuse University College of Medicine, and was the first woman to receive the degree of M.D. in the United States. The first medical school for women was organized in 1850 with a class of seven, the Woman's Medical College of Pennsylvania, and is still

in existence. It is said to be the only medical school for women in the world and to have graduated more than 1,800, including 135 who have become medical missionaries in foreign countries.

During 1939-1940, as shown in table 15, there were 1,145 women studying medicine in the United States,

TABLE 15.—*Women in Medicine in the United States*

1940.....	1,145	5.4	253	5.0

constituting 5.4 per cent of the student enrolment. There were 253 graduates, seven less than in 1939. Of the women matriculants, 103 were in attendance at the one medical college for women while 1,042 were matriculated in sixty-seven schools admitting women. Eighteen were graduated from the Woman's Medical College of Pennsylvania, while 235 secured their degrees from coeducational schools. In the sixteen years since 1925, 3,521 women have graduated in medicine. The decrease in the number of medical students from 1914 to 1918 affected men and women about equally. From 1920 to 1940 the number of women medical students has remained approximately the same. The Council's list of hospitals approved for internships include many that accept women. Statistics compiled by the American Medical Directory revealed that there were 7,470 women physicians in the United States.

Women are admitted to all medical schools of the United States except:

Georgetown University School of Medicine.
Emory University School of Medicine.
Harvard Medical School.
St. Louis University School of Medicine.
Dartmouth Medical School.
Hahnemann Medical College and Hospital of Philadelphia.
Jefferson Medical College.

In addition, two schools which are not coeducational had no women students enrolled, namely the University of North Dakota School of Medicine and West Virginia University School of Medicine.

PART TIME, SPECIAL AND GRADUATE STUDENTS

In forty-seven medical schools of the United States and six in Canada there were, in addition to the regularly enrolled students, 942 part time, special and graduate students pursuing medical subjects, which are tabulated in table 16. This group composes 108 part time, 228 special and 606 graduate students.

The students studying part time were enrolled in twenty-three schools in the United States and one in Canada. The largest group enrolled in any one school

were nineteen studying at the University of Buffalo. Twelve were registered at the University of Kansas and eleven at Wayne University. Less than five were enrolled in fifteen schools.

The 228 special students matriculated in twenty-four schools in the United States and two in Canada. The greatest number (fifty) were at the University of Kansas; at The School of Medicine of the University of Chicago forty-four were in attendance, at the University of North Carolina twenty-three, the University of Tennessee twenty-two, and at Johns Hopkins University seventeen. All other schools registered fewer than eight.

Students registered in the graduate school were pursuing medical subjects in twenty-one medical schools of the United States and four in Canada. There were 606 so registered. At Northwestern University Medical School there were 140 such students. The next highest enrolment was seventy at the University of Toronto Faculty of Medicine, and at Columbia Uni-

versity College of Physicians and Surgeons it was fifty-nine, while other schools had less than fifty.

The University of Oklahoma School of Medicine was the only school which matriculated these three types of students.

Among Canadian schools, one part time, four special and 126 graduate students were enrolled.

SCHOOLS, STUDENTS AND GRADATES, 1905-1940

The number of medical schools, students and graduates in the United States for five year intervals from 1905 to 1920 and for each year since is shown in table 17. In 1905 in the 160 schools then existing there were 26,147. For the academic year just ended there were 21,271 students in seventy-seven schools. This tabulation includes data for only those taking medical courses leading to the M.D. degree and does not include part time and special students, though their work may later be accepted for the M.D. degree. Omitted from these figures also are graduate students.

In the ten years 1910 to 1920 there was a decrease in the enrolment of more than 7,000, while from 1921 to 1935 there was a continuous increase and since 1935 there has been a gradual decrease. In 1940 there were thirty-one fewer enrolled than in 1939 and 1,617 than 1935, 1,293 fewer than 1936, 824 in 1937 and 316 in 1938. The number of medical graduates, however, may not be decreased, since more careful selection will doubtless diminish the number of students who fail to complete their course because of poor scholarship.

TABLE 17.—*Schools, Students and Graduates in the United States, 1905-1940*

1939.....	77	21,302	5,089
1940.....	77	21,271	5,097

* Includes figures for schools of the basic medical sciences.

The number of graduates in 1940 was 5,097, eight more than in 1939, ninety-seven fewer than 1938, 280 less than in 1937. There were 509 fewer graduates in 1939 from sixty-seven schools granting the M.D. degree than in 1905, when there were 160 schools. With the exception of 1933, 1938 and 1939, there has been an increase in the number of medical graduates each year since 1925.

Not shown in the table this year are figures for the year when the lowest number of M.D. degrees was granted. In that year (1922) there were only 2,520 graduates, because of the small size of the class that entered as freshmen in 1918.

The number of medical schools in 1905 was 160; by 1910 the number had dropped to 131 and since 1915 there have been fewer than 100. Since 1933 there have been sixty-six approved four year schools, one offering only clinical courses and ten schools of the basic medical sciences.

In the seventy-seven medical schools in the United States, including the schools of the basic medical sciences, there were 21,271 students and 5,097 graduates.

GRADUATES WITH BACCALAUREATE DEGREES

From the figures contained in table 18 it can be noted that 3,844 of the 5,703 graduates of medical schools in the United States and Canada since July 1, 1939, also held baccalaureate degrees while only five schools require a degree for admission. All the graduates of eleven schools—Stanford, Chicago, Johns Hopkins,

Tufts, Wayne, Cornell, New York University, Western Reserve, Oregon, Jefferson and Woman's—held baccalaureate degrees. Six of these schools either require a degree for admission or will enroll students with three years of college training if the baccalaureate degree is conferred in absentia at the end of the first year in medicine. Four schools in the United States and two in Canada which have a degree requirement accepted altogether twenty-three students with less than the

stated college education. Every medical school had graduates with a baccalaureate degree. The school in the United States having the fewest was the University of Arkansas School of Medicine. Of a class of sixty-three, fourteen had degrees. Queen's University Faculty of Medicine had the fewest of any school in Canada. Only two of the sixty-two graduates were in possession of a college degree. A percentage of 67.4 of all graduates held such degrees.

B.S. IN MEDICINE DEGREE

The graduates of thirty schools in the United States and two in Canada received the Bachelor of Science in Medicine degree. There were 688 awarded in the United States and fifty-eight in Canada. The University of Illinois graduates comprising 110 were the largest single group to obtain this degree. Of the two schools in Canada, one issued fifty-one diplomas. Altogether, a total of 746 Bachelor of Science in Medicine degrees were awarded to 5,703 graduates. However, many schools have discontinued this practice while others have never issued any such degrees.

STUDENTS BY CLASSES, 1930-1939

In table 19 is presented the number of students enrolled in preclinical and clinical classes in the medical schools of the United States by years for each session from 1930-1931 to 1939-1940 inclusive. The total

TABLE 19.—Students in the United States by Years
1930-1940

	Preclinical		Clinical		Intern Year	Total
1930-1931.....	6,450	6,538	5,080	4,908	1,025	23,007

1939-1940.....	5,794*	5,177*	4,921*	4,894*	1,152	22,423

* Excluding enrolment figures for the two medical schools of the University of Chicago, i. e., Rush Medical College 212 and The School of Medicine 273, a total of 485.

attendance for the first preclinical year for the last session was 5,794, forty more than the number enrolled in 1938-1939. Since the year 1933-1934, however, when 6,457 were matriculated, there has been a reduction in this class of 663. In the second preclinical year 5,177 were in attendance in 1939-1940 and, for the two clinical years, 4,921 and 4,894. The two medical schools of the University of Chicago are not operated under the promotion by class system, making it impossible for the schools to report their students in this manner and accordingly they are not included in the figures by classes, but their enrolment is included in the total. Estimates, however, were used in computing totals in 1931, 1934, 1935 and 1938. In 1936, figures for Duke University were also excluded by classes. At Rush Medical College and The School of Medicine of the University of Chicago there were 485 students enrolled during the session just closed, 212 and 273 respectively. By comparison it is noted that the freshman class increased forty, the sophomore enrolment seventeen, the junior and the senior class decreased twenty-six and twenty-seven, respectively, while the number of those interning as a requirement for the M.D. degree remained the same. There was a reduction of thirty-one in the total enrolment of all classes including the intern year.

STUDENTS LEAVING SCHOOL DURING
FIRST TWO YEARS

Of the 6,005 students selected for the freshman class for the session 1935-1936 it is interesting to note that 736 failed or for other reasons did not undertake sophomore studies and further that 1,019 had dropped out by the end of the second medical year. A compari-

TABLE 20.—Students Leaving School During First Two Years

	Class Entering 1935	Class Entering 1937
Freshmen enrolment.....	6,005	5,791
Junior enrolment.....	4,986	4,921
Loss during first two years...	1,019 —870	870
149 fewer students lost dur- ing first two years by the class entering in 1937		

son of the figures for 1935-1936 with those of 1937-1938 is made (table 20), as those entering in the former year would be completing their preclinical course by the latter year.

While 214 fewer freshmen were enrolled in 1937-1938 than in 1935-1936, there were also 149 fewer students who had discontinued their course by the end of the second year. From these figures it is clear that a decrease in the size of the entering class does not mean a corresponding reduction of the number of students in the clinical years. Further, the failure of 17 per cent of the students to continue beyond the second year suggests that many of those who were admitted lacked the ability to meet the exacting requirements of the medical curriculum. Decreases in the entering classes since 1935-1936 may indicate a more careful selection of students, which will result in a smaller number dropping out before the beginning of the junior class and a larger percentage of the class pursuing their course to graduation.

FEEES

In table 21 the eighty-seven medical schools of the United States and Canada, including those offering courses in the basic medical sciences, have been grouped according to the tuition fees charged. To arrive at the figures listed, an average was computed of the resident fees for each school. Two schools have fees under \$100. These were the Universities of North Dakota and Texas. Sixteen schools had fees over \$500, namely the College of Medical Evangelists, Yale, George Wash-

Based on fees charged resident students.

ington, Johns Hopkins, Tufts, St. Louis, Columbia, Cornell, Long Island, New York Medical, New York University, Syracuse, Buffalo, Hahnemann, Pennsylvania and Pittsburgh: Thirty-one schools in the United States and five in Canada made an additional charge for nonresidents ranging from \$37.50 each year by the University of Illinois College of Medicine to \$400 exacted by Louisiana State University. Medical

school fees have been increased, as can be noted by a comparison with a similar tabulation. In 1939 there were three schools in the first group, eight in the second, twenty-two in the third, sixteen in the fourth, twenty-three in the fifth and fifteen in the sixth group.

The lowest nonresident fee in the United States was \$37.50, and in Canada one school has a nonresident fee of \$5 for the first year and \$10 for the second, third and fourth years. Nine schools in the United States and Canada have a nonresident fee of \$99 or less, eighteen have fees between \$100 and \$199, six from \$200 to \$299, two between \$300 and \$399, and one has a fee of \$400.

The average resident fee charged in medical schools in the United States was \$378, whereas in 1939 it was computed at \$353 and in 1938 as \$342.

CITIZENS OF THE UNITED STATES IN FACULTIES OF MEDICINE ABROAD

An inquiry into the number of citizens of the United States studying medicine in faculties of medicine abroad has been carried on by the Council on Medical Education and Hospitals since 1931, when it became evident that great numbers were going to Europe to pursue medical courses. In the spring of 1939, according to incomplete official reports, there were at least 500 at that time in Europe, studying principally in the extramural medical schools of Scotland. Completion of the professional education of these students was interrupted by the decision of the State Department to

discontinue visas of passports to combat areas. Many of these applied to American schools for either advanced credit or admission to the entering class of 1939-1940, with little success. The medical schools of the United States already have many more applications for admission than they can possibly admit and at the time these students were seeking entrance their classes had already been filled to capacity. Some 390 students of the Scottish schools formed an association known as the American Medical Clubs of Scotland and appealed to professional educational agencies for assistance in placing these students. About fifty of the students in their fourth or fifth year were allowed to return to Scotland, leaving approximately 340 students unable to continue their education. The matter was considered at a meeting of the Council on Medical Education and Hospitals held Dec. 10, 1939, and it was felt that the question of accepting transfers from these institutions is a matter which should be left to the consideration of the individual medical schools of this country. Similar action was taken by other bodies. At a conference in March 1940 the State Department agreed that for the present at least it would issue visas for Switzerland for the students who wish to continue their studies in that country. It was estimated that about 100 of the group will avail themselves of this possibility. With the movement of events in Europe in recent months it is quite evident that it will be impossible for students from this country to obtain a medical education in Europe in the near future.

DESCRIPTION OF MEDICAL SCHOOLS

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 29 professors and 102 lecturers and assistants, total 131. The curriculum covers four years of nine months each. Entrance requirements are two years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The fees for the four years for residents of Arkansas are \$280; nonresidents are charged \$225 additional each year. The registration for 1939-1940 was 278; graduates, 63. The next session begins Sept. 25, 1940, and ends June 10, 1941. The Dean is Stuart P. Cromer, M.D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, University Campus, Berkeley; Medical Center, San Francisco.—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California, at Los Angeles, became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged, and elective chairs in homoeopathic materia medica, and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The faculty is composed of 154 professors and 302 associates and assistants, a total of 456. The course covers four years of eight months each, and an additional fifth year consisting of an internship in a hospital or of special work in a department of the medical school. Fees for the four years, respectively, for residents of California are \$277, \$240, \$235 and \$235; nonresidents are charged \$300 additional each year. The registration for 1939-1940 was 241; graduates, 60. The next session begins Aug. 26, 1940, and ends May 24, 1941. The Acting Dean is President Robert G. Sproul, LL.D., Berkeley.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS, Loma Linda; Boyle and Michigan Aves., Los Angeles.—Organized in 1909. The first class graduated in

1914. The laboratory departments are at Loma Linda, the clinical departments at Los Angeles. Coeducational since organization. The faculty is composed of 49 professors and 337 associates, assistants and instructors, a total of 386. The course covers a period of four years of nine months each and an additional year consisting of an internship in an approved hospital. Sixty-four semester hours of collegiate work are required for admission. The total fees are respectively, \$612, \$601, \$611 and \$611. The registration for 1939-1940 was 316; graduates, 101. The next session begins Sept. 2, 1940, and ends June 1, 1941. The President is Percy T. Magan, M.D., Los Angeles. The Dean is E. H. Risley, M.D., Loma Linda; the Associate Dean is W. E. Macpherson, M.D., Los Angeles.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE, 3551 University Avenue.—Organized in 1885 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908, it became the Los Angeles Medical Department of the University of California. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920; reorganized in May 1928, under present title. The faculty consists of 144 professors and 180 instructors, assistants and others, a total of 324. An internship is required for graduation. Three years of collegiate work are required for admission. Coeducational since organization. Annual fees amount to \$452. The registration for 1939-1940 was 202; graduates, 43. The next session begins Sept. 16, 1940, and ends June 7, 1941. The Dean is Paul S. McKibben, Ph.D.

Stanford University-San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE, University Campus, Stanford University; 2398 Sacramento Street, San Francisco. The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry, and physiology are located on the campus at Stanford University, which is thirty miles southeast of San Francisco adjoining the City of Palo Alto. The post office is Stanford University. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 132 professors and 144 lecturers, assistants and others, a total of 276. Three years of collegiate work are required for admission. The course covers four years of eight and one-half months each, plus a fifth year of intern work. The fees for the four years, respectively, are \$530, \$458, \$409 and \$409. The registration for 1939-1940 was 240; graduates, 55. The next session begins Sept. 24, 1940, and ends June 15, 1941. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged, Jan. 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants, a total of 187. The course covers four years of nine months each. The entrance requirements are three years of collegiate work. The fees for residents of Colorado are, respectively, \$301, \$296, \$281 and \$281. Nonresidents are charged \$245 additional each year. The registration for 1939-1940 was 204; graduates, 51. The next session begins Sept. 23, 1940, and ends June 9, 1941. The Dean is Maurice H. Rees, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE, 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812; instruction began in 1813; first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The faculty consists of 178 professors and 220 lecturers and assistants, a total of 398. The requirements for admission are three years of collegiate work. The course covers four years of nine months each. The fees are, respectively, \$505, \$500, \$500, and \$520. The registration for 1939-1940 was 208, graduates, 44. The next session begins Sept. 23, 1940, and ends June 11, 1941. The Acting Dean is Francis G. Blake, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 3900 Reservoir Road, N.W.—Organized in 1851. First class graduated in 1852. The faculty is composed of 64 professors, 42 associate professors, 12 assistant professors, 5 adjunct professors, and 121 instructors, total 244. A baccalaureate degree is required for admission. The course of study covers four terms of eight and one-half months each. The present fees for each of the four sessions are \$500. The registration for 1939-1940 was 326; graduates, 80. The next session begins Sept. 23, 1940, and ends June 1, 1941. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, 1335 H Street, N.W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except in 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904, by an Act of Congress, the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 74 professors and 137 instructors, demonstrators and assistants, a total of 211. Two years of collegiate work are required for admission. The course covers four years of thirty-six weeks each. The fees for each of the four years are \$550. The registration for 1939-1940 was 248; graduate, 48. The next session begins Sept. 23, 1940, and ends June 11, 1941. The Dean is Walter A. Bloedorn, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE, Fifth and W Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 30 professors and 67 instructors and assistants, 97 in all. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. The fees are, respectively, \$269, \$269, \$259 and \$266. Registration for 1939-1940 was 119; graduates, 33. The next session begins Sept. 23, 1940, and ends June 13, 1941. The Dean is Numa P. G. Adams, M.D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE, 50 Armstrong Street.—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915; assumed present title in 1917. Three years of collegiate work are required for admission. The faculty consists of 16 professors and 176 associates and assistants, a total of 192. The course of study is four years of thirty-two weeks each. The fees for each of the four years are \$338. The registration for 1939-1940 was 219; graduates, 50. The next session begins Sept. 26, 1940, and ends June 9, 1941. The Dean is Russell H. Oppenheimer, M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. Since 1873 it has

been known as the Medical Department of the University of Georgia, the name being changed July 1, 1933, to the University of Georgia School of Medicine. Properly transferred to the University in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 60 professors and 29 assistants, 89 in all. Three years of collegiate work are required for admission. The course is four years of thirty-four weeks each. The fees for each of the four years are \$225 for residents of Georgia, and \$445 each year for nonresidents. The registration for 1939-1940 was 166; graduates, 33. The next session begins Sept. 26, 1940, and ends June 9, 1941. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Wolcott Avenue.—Incorporated in 1915 as the Bennett Medical College, and operated as an organic part of Loyola University, by virtue of an agreement entered into with the trustees of Bennett Medical College. Present title assumed in 1917. The Chicago College of Medicine and Surgery was purchased in 1917. The first class graduated in 1916. Coeducational. Three years of collegiate work are required for admission. The course of study is five years, including an internship. The faculty is composed of 88 in professorial rank and 209 others, a total of 297. The fees for each year are \$510, \$515, \$455 and \$372 respectively. The enrollment for 1939-1940 was 302; graduates, 115. Next session for seniors begins Oct. 21, 1940, for juniors Sept. 23, 1940, for freshmen and sophomores, Sept. 16, 1940, and ends June 11, 1941. The Dean is Louis D. Moorhead, M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises 136 professors, 356 associates and instructors, a total of 492. The requirement for admission is three years of collegiate work. The B.S. degree in medicine may be conferred before the end of the senior year. The course covers four years of eight and one-half months each and a fifth year spent in an approved hospital as an intern or in other practical work. The total fees are \$414 each year. The registration for 1939-1940 was 556; graduates, 156. The next session begins Oct. 1, 1940, and ends June 14, 1941. The Dean is Irving S. Cutter, M.D.

UNIVERSITY OF CHICAGO, THE SCHOOL OF MEDICINE, Fifty-Eighth Street and Ellis Avenue, Chicago.—Organized in 1924, as a part of the Ogden Graduate School of Science of the University of Chicago. In 1932, when the University of Chicago reorganized its departments, the medical departments were included in the Biological Sciences Division and the school is now officially the School of Medicine of the Division of Biological Sciences of the Ogden Graduate School of Science. It is designated in publications as the School of Medicine of the University of Chicago. The work of the first two years in the medical courses has been given on the University Quadrangles since 1899; but the last two years were offered only at Rush Medical College which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time, candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. Undergraduate courses in the clinical years at Rush Medical College will terminate in June 1942, when the students now enrolled will complete their studies. All undergraduate instruction will thereafter be given only on the campus, and Rush will become a post-graduate school. The faculty of the School of Medicine is composed of 108 professors, 163 associates, instructors and others, a total of 271. The requirements for admission are three years of collegiate work. The B.S. degree in medicine may be obtained during the second year. The curriculum covers twelve quarters of work. Students are admitted at the beginning of Spring, Summer and Autumn quarters. Sixty-five students are admitted to first year classes in each calendar year. The tuition fee for each of the four years is \$450. The registration for 1939-1940 was 273; graduates, 35. The next session begins Sept. 30, 1940, and ends June 11, 1941. All correspondence relating to general policies should be addressed to W. H. Taliaferro, Ph.D., Dean of the Division of Biological Sciences, or to A. C. Bachmeyer, M.D., Associate Dean, and that pertaining to student affairs should be addressed to Victor Johnson, M.D., Dean of Medical Students.

RUSH MEDICAL COLLEGE, 1758 West Harrison Street, Chicago.—Chartered in 1837 and taught first class in 1843. First class graduated in 1844. In 1887 the College became the medical department of Lake Forest University, retaining, however, its self-government. This relationship was dissolved in April 1898, and in the same month affiliation with the University of Chicago was established. Since 1899 the first two years of the medical course have been given on the university campus. Clinical years only were offered at Rush Medical College. In May 1924, under a new agreement, the University of Chicago took over the work of Rush Medical College as a department of the university. The faculty is composed of 143 professors, 155 associates, instructors and others, a total of 298. The tuition fee is \$450 yearly. The registration for 1939-1940 was 212; graduates, 106. The next session begins Sept. 30, 1940, and ends June 11, 1941. The school is in session all year except the month of September. By resolution of the board of trustees of the University of

Chicago, undergraduate courses in the clinical years will terminate in June 1942, when the students now enrolled in these courses will have completed their studies. The college is now designated The Rush Graduate School of Medicine. Graduate courses are being organized. Wilber E. Post, M.D., has been appointed dean of the Graduate School. The Acting Dean of Rush Medical College is Earle Gray, M.D.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, 1853 West Polk Street.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was cancelled in June 1912, and was restored in March 1913, when the present title was assumed. Coeducational since 1898. Three years of collegiate work are required for admission. The curriculum covers four years of thirty-two weeks each, and a year of internship in an approved hospital. The B.S. degree in medicine is conferred at the end of the second year. The faculty is composed of 143 professors and 325 associates, instructors and assistants, a total of 468. The tuition is \$150 a year for students who are residents of Illinois; \$225 a year for nonresident students. The registration for 1939-1940 was 636; graduates, 162. The next session begins Sept. 23, 1940, and ends June 6, 1941. The Dean is David J. Davis, M.D.

INDIANA

Bloomington-Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE, Bloomington; 1040 West Michigan Street, Indianapolis.—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana organized in 1878, the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The faculty consists of 270 professors, lecturers, associates and assistants. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred. The work of the first year is given at Bloomington and the work of the next three years at Indianapolis. The regular fee for the medical course for all four years is \$217 a year for residents of Indiana, and \$422 for nonresidents. The registration for 1939-1940 was 460; graduates, 105. The next session begins Sept. 14, 1940, and ends June 2, 1941. The Dean is Willis D. Gatch, M.D., Indianapolis.

IOWA

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. The faculty is made up of 56 professors, 74 lecturers, demonstrators and assistants, a total of 130. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. The course of study covers four years of thirty-four weeks each. The tuition fee is \$196 each year for residents of Iowa and \$460 for nonresidents. The registration for 1939-1940 was 293; graduates, 71. The next session begins Sept. 26, 1940, and ends June 2, 1941. The Dean is Ewen Murchison MacEwen, M.D.

KANSAS

Lawrence-Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE, Lawrence; 39th Street and Rainbow Boulevard, Kansas City.—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College in 1913. The first class graduated in 1906. The clinical courses are given at Kansas City. Coeducational since 1880. The faculty includes 65 professors and 140 instructors, assistants and others, a total of 205. The requirement for admission is three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The course covers four years of nine months each. The total fees for residents of the state are, respectively, \$157, \$163, \$165 and \$167. For nonresidents the fees are, respectively, \$267, \$343, \$415 and \$417. The registration for 1939-1940 was 294; graduates, 69. The next session begins Sept. 19, 1940, and ends June 9, 1941. The Dean is H. R. Wahl, M.D., Kansas City.

KENTUCKY

Louisville

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE, 101 West Chestnut Street.—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department; in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922

it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of collegiate work are the minimum requirement for admission. Preference is given applicants with a degree or three college years leading to a degree. The faculty numbers 77 professors, and 116 assistants, instructors and others, a total of 193. Course covers four years of thirty-two weeks each, exclusive of vacations and examinations. Fees are, respectively, \$450, \$450, \$450 and \$460. The registration for 1939-1940 was 341, graduates, 84. The next session begins Sept. 23, 1940, and ends May 31, 1941. The Dean is John Walker Moore, M.D.

LOUISIANA

New Orleans

LOUISIANA STATE UNIVERSITY SCHOOL OF MEDICINE, 1542 Tulane Avenue.—Organized January 1931 as Louisiana State University Medical Center. Present title in 1939. Coeducational. First session October 1931, with students of first and third year. Faculty comprises 34 professors and 171 assistant professors, instructors and assistants, a total of 205. Course covers four years of no less than 32 weeks each. A minimum of three years' collegiate work is required for admission. Total fees, \$133 each year for residents of Louisiana; additional tuition of \$400 each year for nonresidents. The registration for 1939-1940 was 351; graduates, 136. The next session begins Sept. 9, 1940, and ends May 31, 1941. The Dean is B. I. Burns, M.D.

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE, 1430 Tulane Avenue.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863-1865, inclusive. It was transferred to the Medical Department of the University of Louisiana in 1847, and became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. The faculty comprises 29 professors and 206 associate and assistant professors, instructors and assistants, a total of 235. The course covers four years of thirty-two weeks each. A minimum of three years of collegiate work is required for admission. Total fees are, respectively, \$552, \$552, \$537 and \$547. The registration for 1939-1940 was 471; graduates, 120. The next session begins Sept. 26, 1940, and ends June 11, 1941. The Dean is Maxwell E. Lapham, M.D.

MARYLAND

Baltimore

JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE, 710 North Washington Street.—The nucleus of a Medical Faculty was constituted in 1883. Systematic postgraduate instruction in pathology and bacteriology was begun in 1886. School was fully organized and opened in 1893. The first class graduated in 1897. Coeducational since organization. The faculty consists of 71 professors and 405 instructors, assistants and others, a total of 476. The requirement for admission is a collegiate degree. The course extends over four years of eight and one-half months each. The total fees are, respectively, \$621, \$620, \$620 and \$620. The registration for 1939-1940 was 279; graduates, 68. The next session begins Sept. 24, 1940, and ends June 3, 1941. The Dean is Alau M. Chesney, M.D.

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS, Lombard and Greene Streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged with it in 1913. In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed. Coeducational since 1918. The faculty consists of 49 professors and 272 associate and assistant professors and others, a total of 321. Three years of collegiate work are required for admission. The course covers four years of eight months each. The fees are, respectively, \$506, \$493, \$492 and \$512 for residents of the state; for nonresidents the fees are \$150 additional each year. The registration for 1939-1940 was 370; graduates, 100. The next session begins Sept. 26, 1940 and ends June 7, 1941. The Acting Dean is H. Boyd Wyllie, M.D.

MASSACHUSETTS

Boston

BOSTON UNIVERSITY SCHOOL OF MEDICINE, 80 East Concord Street.—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Three years of collegiate work are required for admission. The faculty includes 25 professors, 175 associates and others, a total of 200. The course covers four years. Total fees for each of the four years, respectively, are \$479, \$475, \$475, \$440. The registration for 1939-1940 was 205; graduates, 54. The next session begins Sept. 26, 1940, for 1st, 2d and 3d year students, and Sept. 16, 1940, for 4th year students, and ends June 16, 1941. The Dean is Alexander S. Begg, M.D.

HARVARD MEDICAL SCHOOL, 25 Shattuck Street.—Organized in 1782. The first class graduated in 1788. It has a faculty of 162 professors and 445 other instructors and assistants, a total of 607. Two years of collegiate work are required for admission. The total fees for each of the four years are \$420, plus \$5 the first year for matriculation. The registration for 1939-1940 was 522; graduates, 132. The next session begins Sept. 23, 1940, and ends June 19, 1941. The Dean is C. Sidney Burwell, M.D.

TUFTS COLLEGE MEDICAL SCHOOL, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. It has a faculty of 88 professors and 293 assistants, lecturers and others, a total of 381. A bachelor's degree is required for admission. The course covers four years of eight months each. The total fees for each of the four years are \$512, \$507, \$507 and \$517. The registration for 1939-1940 was 386; graduates, 96. The next session begins Sept. 18, 1940, and ends June 15, 1941. The Dean is A. Warren Stearns, M.D.

MICHIGAN

Ann Arbor

UNIVERSITY OF MICHIGAN MEDICAL SCHOOL.—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. Coeducational since 1870. It has a faculty of 27 professors, 21 associate professors, 25 assistant professors, 126 assistants, instructors and lecturers; a total of 199. The entrance requirements are ninety semester hours. The curriculum covers four years of nine months each. The total fees for Michigan students are \$250 for each of the four years, respectively; for nonresidents \$400 a year. The registration for 1939-1940 was 466; graduates, 125. The next session begins Sept. 30, 1940, and ends June 21, 1941. The Dean is A. C. Furstenberg, M.D.

Detroit

WAYNE UNIVERSITY COLLEGE OF MEDICINE, 1516 St. Antoine Street.—Organized as the Detroit College of Medicine in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1886. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by action of the Detroit Board of Education to Wayne University College of Medicine, as a part of the program of consolidation of the Detroit City Colleges into a university system. Coeducational since 1917. Entrance requirement is an academic degree or 90 semester hours of academic credit with "combined degree" guaranteed by school of arts and sciences. The faculty consists of 48 professors, 243 lecturers and others, a total of 291. The course covers four years of nine months each and a fifth year of intern work. The total fees for each of the first four years are, for Wayne County residents \$325, and for nonresidents outside of Wayne County \$425; for the fourth year a diploma fee of \$10.00. The registration for 1939-1940 was 245; graduates, 60. The next session begins Sept. 16, 1940, and ends June 14, 1941. The Dean is Edgar H. Norris, M.D.

MINNESOTA

Minneapolis

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL.—Organized in 1883 as the University of Minnesota College of Medicine and Surgery, reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. The faculty includes 204 professors, of whom 77 are on full time appointment and 127 on part time, and 134 instructors, 29 of whom are on full-time appointment and 105 on part time, a total of 338. The curriculum covers four years of nine months each, and a year's internship in an approved hospital. The school is operated on the four-quarter plan. The entrance requirements are three years of university work, which must include six semester credits of rhetoric, eight semester credits of physics; thirteen credits of general chemistry, qualitative and quantitative analysis, organic and physical chemistry; eight credits of general zoology and genetics and eugenics; four credits of general psychology, and a reading knowledge of scientific German, with a "C" average in all subjects and in the sciences. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Bachelor of Medicine (M.B.), which is granted at the end of the four-year course. The M.D. degree is conferred after a year of intern work, of advanced laboratory work, or of public health work has been completed. Students are graduated at the end of any quarter in which work is completed and examinations passed. Total fees are \$250 for residents and \$400 for nonresidents, each year of three quarters. The registration for 1939-1940 was 454; graduates, 104. The next session begins Sept. 30, 1940, and ends June 13, 1941. The Dean is Harold S. Diehl, M.D.

MISSOURI

St. Louis

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, 1402 South Grand Boulevard. Organized in 1901 as the Marion-Sims-Beaumont Medical College by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the Medical School of St. Louis University in 1903. The faculty is composed of 76 professors and 247 instructors and assistants, a total of 323. The completion of three years of college study is the minimum admission requirement but students presenting meritorious credits in excess of the minimum are accepted by preference. The curriculum covers four years of thirty-two weeks each. The summer is optional and offers courses academically equivalent to those in the regular

session. The total fees are, respectively, \$530, \$525, \$525 and \$565. The registration for 1939-1940 was 418; graduates, 106. The next session begins Sept. 24, 1940, and ends June 1, 1941. The Dean is Alphonse M. Schwittalla, S.J., Ph.D.

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, Kingshighway and Euclid Avenue.—Organized in 1842 as the Medical Department of St. Louis University. The first class graduated in 1843. In 1853 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1918. The faculty comprises 127 professors and 238 lecturers, instructors and others, a total of 365. Four years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the third or fourth year. The course is four years of eight months each. The total fees are, respectively, \$524, \$519, \$519 and \$424. The registration for 1939-1940 was 345; graduates, 95. The next session begins Sept. 26, 1940, and ends June 10, 1941. The Dean is Philip A. Shaffer, Ph.D.

NEBRASKA

Omaha

CREIGHTON UNIVERSITY SCHOOL OF MEDICINE, 306 North Fourteenth Street.—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. It has a faculty of 72 professors and 75 instructors, lecturers and assistants, a total of 147. Three years of collegiate work required for admission. The B.S. degree in medicine is conferred at the end of the second year. The curriculum covers four years of eight months each. The total fees for the four years are, respectively, \$392, \$393, \$348 and \$356, and \$100 additional each year for students who have not taken the major part of their work at Creighton University School of Arts and Sciences. The registration for 1939-1940 was 231; graduates, 57. The next session begins Sept. 24, 1940, and ends June 5, 1941. The Dean is Charles M. Wilhelmj, M.D.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Forty-Second Street and Dewey Avenue.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. The faculty is composed of 72 professors and 57 lecturers and instructors, a total of 129. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees for the four years, respectively, are \$219, \$214, \$214 and \$214. The registration for 1939-1940 was 320; graduates, 76. The next session begins Sept. 23, 1940, and ends June 9, 1941. The Dean is C. W. M. Poynter, M.D.

NEW YORK

Albany

ALBANY MEDICAL COLLEGE, 47 New Scotland Avenue.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The faculty is composed of 75 professors and 122 instructors, assistants and others, a total of 197. A collegiate degree is required for admission. The curriculum covers four years of eight months each. The total fees are, respectively, \$455, \$430, \$415 and \$425. The registration for 1939-1940 was 128; graduates, 29. The next session begins Sept. 9, 1940, and ends June 9, 1941. The Dean is R. S. Cunningham, M.D.

Brooklyn

LONG ISLAND COLLEGE OF MEDICINE, 350 Henry Street.—Organized in 1858 as the Long Island College Hospital. The first class graduated in 1860 and the last class in 1930. Reorganized with a new charter in 1930 as the present institution. The first class graduated in 1931. Coeducational. It has a faculty of 119 professors, associate, assistant, clinical and assistant clinical professors, and 185 lecturers, associates, instructors, assistants and others, a total of 304. Ninety semester hours of collegiate work are required for admission. The course covers four years. The total fee for each of the four years is \$610. The registration for 1939-1940 was 354; graduates, 81. The next session begins Sept. 9, 1940, for the fourth year and Sept. 23, 1940, for the other years, and ends June 7, 1941. The Dean is Jean Alonzo Curran, M.D.

Buffalo

UNIVERSITY OF BUFFALO SCHOOL OF MEDICINE, 24 High Street.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The faculty is composed of 86 professors and 193 associates, assistants and others, a total of 279. Two years of collegiate work are required for admission. The course covers four years of eight months each. The total fees are, respectively, \$530, \$525, \$520 and \$530. The registration for 1939-1940 was 259; graduates, 56. The next session begins Sept. 30, 1940, and ends June 7, 1941. The Dean is Edward W. Koch, M.D.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 11 West One Hundred and Sixty-Eighth Street.—The medical faculty of Columbia College, then known as King's College, was organized in 1767.

Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. The faculty is composed of 278 professors and 549 instructors, demonstrators and others, a total of 827. Three years of collegiate work are required for admission. The work covers four years of eight months each. The total fees are, respectively, \$545, \$530, \$530 and \$550. The registration for 1939-1940 was 413; graduates, 102. The next session begins Sept. 19, 1940, and ends June 3, 1941. The Dean is Willard C. Rappleye, M.D.

NEW YORK MEDICAL COLLEGE, FLOWER AND FIFTH AVENUE HOSPITALS, 1 East 105th Street.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869; the title New York Homeopathic Medical College and Hospital in 1887; the title New York Homeopathic Medical College and Flower Hospital in 1908; the title New York Medical College and Flower Hospital in 1936; the present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. A baccalaureate degree or its equivalent required for admission. The course covers four years of eight months each. It has a faculty of 69 professors and associate professors, 29 assistant professors, and 228 lecturers and assistants, a total of 326. The fees are, respectively, \$645, \$635, \$635 and \$665. The registration for 1939-1940 was 278; graduates, 50. The next session begins Sept. 16, 1940, and ends June 6, 1941. The President is Claude A. Burrett, M.D.

NEW YORK UNIVERSITY COLLEGE OF MEDICINE, 477 First Avenue.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. Named University and Bellevue Hospital Medical College from 1898 to February 1935 when it was changed to New York University College of Medicine. First class graduated in 1899. Coeducational since 1919. The faculty is composed of 140 professors, associate, assistant, clinical and assistant clinical professors, and 379 lecturers, instructors and others, a total of 519. The course covers four years. Entrance requirements are that all candidates must have completed three full years of study in an approved college of arts and sciences. The fees for each of the four years are \$600. The registration for 1939-1940 was 495; graduates, 124. The next session begins Sept. 18, 1940, and ends June 11, 1941. The Dean is Currier McEwen, M.D.

CORNELL UNIVERSITY MEDICAL COLLEGE, 1300 York Avenue.—Organized in 1898. Coeducational since organization. The first year was given to approximately one-third of the class at Ithaca, but in 1938 this branch was discontinued and all work is now given in New York City. The faculty is composed of 135 professors and 304 assistants, lecturers, instructors, and others, a total of 439. All candidates for admission must be graduates of approved colleges or scientific schools, or seniors of approved colleges that will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the baccalaureate degree on the completion of the first year's work. The fees are, respectively: \$620, \$610, \$515 and \$525. The registration for 1939-1940 was 292; graduates, 70. The next session begins Sept. 17, 1940, and ends June 11, 1941. The Dean is William S. Ladd, M.D.

Rochester

UNIVERSITY OF ROCHESTER SCHOOL OF MEDICINE AND DENTISTRY, 260 Crittenden Boulevard.—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. The faculty is composed of 66 professors, 200 lecturers, assistants, instructors and others, a total of 266. The work embraces a graded course of four years of nine months each. Three years of collegiate work are required for admission. The total fees for each year are \$500. The registration for 1939-1940 was 200; graduates, 45. The next session begins Sept. 16, 1940, and ends June 14, 1941. The Dean is George Hoyt Whipple, M.D.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE, 766 Irving Avenue.—Organized in 1872, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875, when a compulsory three-year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. The faculty is composed of 48 professors and 172 associate and assistant professors, lecturers and instructors, a total of 220. Three years of a recognized college course are required for admission. The course covers four years of thirty-four weeks each. The fee for each of the first three years is \$500; for the fourth year, \$510. The enrolment for 1939-1940 was 170; graduates, 40. The next session begins Sept. 16, 1940, and ends June 2, 1941. The Dean is H. G. Weiskotten, M.D.

NORTH CAROLINA

Durham

DUKE UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1925. The first class was admitted, Oct. 1, 1930. Coeducational. The faculty is composed of 12 professors and 144 associate and assistant professors, lecturers, instructors and assistants, a total of 156. The entrance require-

ments are ninety hours of collegiate work. The academic year consists of four quarters of eleven weeks each. Students either may study four quarters each year after the first year, and if satisfactory will receive the M.D. certificate after three and one quarter calendar years, or three quarters in each year, and if satisfactory will be graduated after four calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. The fees are \$450 for each year of three quarters. The registration for 1939-1940 was 259; graduates, 58. The next session begins Oct. 3, 1940, and ends June 6, 1941. The Dean is Wilburt C. Davison, M.D.

OHIO

Cincinnati

UNIVERSITY OF CINCINNATI COLLEGE OF MEDICINE, Eden and Bethesda Avenues.—Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged with the University when the title of Ohio-Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Candidates for admission to the freshman class must present three years of college preparation of not less than ninety hours. Liberal Arts students of the University of Cincinnati may sign up for the seven-year combined Liberal Arts and Medical program. The B.Sc. degree is granted on the joint recommendation of the Faculties of the Colleges of Liberal Arts and Medicine at the end of the first medical year. The faculty consists of 112 professors, associate and assistant professors, 350 instructors, etc., a total of 462. The course covers four years of eight months each, on the completion of which the M.B. degree is granted. A year's internship in an approved hospital is required, on completion of which the M.D. degree is granted. Beginning with the fall session of 1940-1941 the fees will be as follows: For legal residents of Cincinnati \$485 a year, plus laboratory fees, (\$50 additional for those not legal residents of Cincinnati). The registration for 1939-1940 was 303; graduates, 66. The next session begins Sept. 20, 1940, and ends June 6, 1941. The Dean is Stanley Dorst, M.D.

Cleveland

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE, 2109 Adelbert Road.—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844. It assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. The faculty includes 89 professors and 233 lecturers, assistants and others, a total of 322. The curriculum covers three years of nine months each and one year of ten months. Three years of collegiate work are required for admission and a baccalaureate degree for graduation. The total fees are, respectively, \$442, \$430, \$415 and \$425. Beginning with the academic session of 1941-1942, the tuition fee will be increased by \$100 for each year. The registration for 1939-1940 was 265; graduates, 58. The next session begins Sept. 19, 1940, and ends June 11, 1941. The Dean is Torald Sollmann, M.D.

Columbus

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE, Neil and Eleventh Avenues.—Organized in 1907 as the Starling-Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter granted by the State Legislature changing the name from Willoughby Medical College, which was chartered March 3, 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. The faculty consists of 76 professors, associate and assistant professors, 96 lecturers, instructors, demonstrators and others, a total of 172. Three years of collegiate work are required for admission. The course covers four years of thirty-four weeks each. Tuition fees are \$327 for the first year, and \$312 for each of the other three years for residents of Ohio, and \$150 additional for nonresidents. The registration for 1939-1940 was 307; graduates, 77. The next session begins Oct. 1, 1940, and ends June 16, 1941. The Dean is J. H. J. Upham, M.D.

OKLAHOMA

Oklahoma City

UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE, 801 East Thirteenth Street.—Organized in 1900. Until 1910 gave only the first two years of the medical course at Norman, Oklahoma, after which a clinical department was established at Oklahoma City. The first class graduated in 1911. Coeducational since organization. Since September 1928 the entire four-year course has been given in Oklahoma City. It has a faculty of 27 professors, 28 associate professors, 18 assistant professors, 32 associates, 15 lecturers, 36 instructors, and 24 assistants, a total of 180. Three years of college work are required for admission. The B.S. in Medicine will not be conferred after 3 years, 1940. The course covers four years of nine months each. Fees: \$50.00 "Maintenance and Incidental Fee" per semester, which began with the freshman class of 1939-1940. Other annual course fees average \$128, \$95, \$53, and \$58, in the order given, beginning with the freshman year. For students not residents of

Oklahoma there is a tuition charge of \$350 a year, plus laboratory and course fees as indicated for the different years. The registration for 1939-1940 was 231; graduates, 52. The next session begins Sept. 16, 1940, and ends June 9, 1941. The Dean is Robert U. Patterson, M.D., C.M.

OREGON

Portland

UNIVERSITY OF OREGON MEDICAL SCHOOL, Marquam Hill.—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. It has a faculty of 91 professors and 164 lecturers, assistants and others, a total of 255. Entrance requirements are three years of collegiate work. The course covers four years of thirty-three weeks each. The total fees are, respectively, \$380, \$375, \$370 and \$376 for residents of Oregon, and \$60 a year additional for nonresidents. The registration for 1939-1940 was 240; graduates, 49. The next session begins Oct. 1, 1940, and ends June 10, 1941. The Dean is Richard B. Dillehunt, M.D.

PENNSYLVANIA

Philadelphia

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF PHILADELPHIA, 235 North Fifteenth Street.—Organized in 1848 as The Homeopathic Medical College of Pennsylvania. In 1869 it united with The Hahnemann Medical College of Philadelphia, taking the latter title. Assumed present title in 1885. The first class graduated in 1849. Three years of collegiate work in a college of arts and sciences are required for admission. It has a faculty of 80 professors and 158 lecturers, instructors, and others, a total of 238. The work covers four years of eight months each. Fees are, respectively, \$515, \$512, \$512 and \$535. The registration for 1939-1940 was 543; graduates, 127. The next session begins Sept. 30, 1940, and ends June 12, 1941. The Dean is William A. Pearson, M.D.

JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, 1025 Walnut Street.—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa. It was chartered with its present title in 1838. Classes have been graduated annually beginning 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its own board of trustees. It has a faculty of 83 professors, associate and assistant professors and 192 associates, lecturers, demonstrators and instructors, a total of 275. Four years of college work and a bachelor's degree are required for admission. The course of study covers four years of eight and one-half months each. The total fees are, respectively, \$455, \$440, \$430 and \$430. The registration for 1939-1940 was 497; graduates, 125. The next session begins Sept. 18, 1940, and ends June 6, 1941. The Dean is Henry K. Mohler, M.D.

TEMPLE UNIVERSITY SCHOOL OF MEDICINE, 3400 North Broad Street.—Organized in 1901. The first class graduated in 1904. Coeducational since organization. The faculty numbers 34 professors and 232 associates, assistants and others, a total of 266. Three years of collegiate work are required for admission. The fees for each of the four years, respectively, are \$500, \$490, \$480 and \$500. The registration for 1939-1940 was 446; graduates, 119. The next session begins Sept. 18, 1940, and ends June 12, 1941. The Dean is William N. Parkinson, M.D.

UNIVERSITY OF PENNSYLVANIA SCHOOL OF MEDICINE, Thirty-Sixth and Pine Streets.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772 and 1775-1779, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title was adopted in 1909. It granted the first medical diploma issued in America. In 1916 it took over the Medico-Chirurgical College of Philadelphia to develop it as a graduate school. Coeducational since 1914. The faculty consists of 106 professors, associate and assistant professors, and 412 lecturers, associates, instructors and others, a total of 518. Three years of collegiate work are required for admission. The course covers four years of thirty-three weeks each. The tuition fee is \$500 each year, with a deposit fee of \$15, a general fee including student health of \$15 and a matriculation fee of \$5. The registration for 1939-1940 was 491; graduates, 134. The next session begins Sept. 23, 1940, and ends June 11, 1941. The Dean is William Pepper, M.D.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, Henry Avenue and Abbottsford Road, East Falls.—Organized in 1850. Classes were graduated in 1852 and in all subsequent years except 1862. It has a faculty of 48 professors and 80 assistants, lecturers and others, in all, 128. Three years of collegiate work are required for admission. The curriculum covers four years of eight and one-half months each. Total fees are, respectively, \$447, \$433, \$433, \$455. The registration for 1939-1940 was 103; graduates, 18. The next session begins Sept. 18, 1940, and ends June 11, 1941. The Interim Dean is Catharine Macfarlane, M.D.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Bigelow Boulevard.—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducational since 1899. The faculty is composed of 31 professors and 331 associates, assistants and others, a total of 362. Entrance requirements are two years of collegiate work. The course of study is

four years of eight months each. The total fees are \$500 each year. The registration for 1939-1940 was 257; graduates, 46. The next session begins Sept. 23, 1940, and ends June 11, 1941. The Dean is W. S. McEllroy, M.D.

SOUTH CAROLINA

Charleston

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, 16 Lucas Street.—Organized in 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1832 a medical college bearing the present title was chartered and the two schools continued as separate institutions until they were merged in 1838. Classes were graduated in all years except 1862 to 1865, inclusive. In 1913, by legislative enactment, it became a state institution. Coeducational from 1895 to 1912, when privileges for women were withdrawn, being restored in 1917. It has a faculty of 46 professors and 45 associates, instructors and others, a total of 91. The course covers four years of eight months each. Three years of collegiate work are required for admission. The total fees are \$272 each year. Fees for nonresidents of the state, \$422 each year. The enrollment for 1939-1940 was 171; graduates, 40. The next session begins Sept. 26, 1940, and ends June 5, 1941. The Dean is Robert Wilson, M.D.

TENNESSEE

Memphis

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, 874 Union Avenue.—Organized in 1876 at Nashville as Nashville Medical College. First class graduated 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. Coeducational since 1911. The faculty includes 104 professors and 146 assistants, instructors and others, a total of 250. Two years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees are \$120 quarterly. For residents of the state the charge is reduced \$50 each quarter. The registration for 1939-1940 was 439; graduates, 96. During the academic year of 1940-1941 the quarters begin July 5, Sept. 23, Dec. 30 and March 20, and end Sept. 21, Dec. 11, March 19 and June 7. The Dean is O. W. Hyman, Ph.D.

Nashville

MEHARRY MEDICAL COLLEGE, Eighteenth Avenue, North and Jefferson Street. (For Negro Youth).—This school was organized in 1876 as the Meharry Medical Department of Central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1915. Coeducational since 1876. The faculty is made up of 49 professors and 30 instructors and lecturers, 79 in all. Three years' work in a college of liberal arts is required for admission. The curriculum covers four years of thirty-two weeks each. Tuition fees are, respectively, \$300, \$290, \$280 and \$290 each year. The registration for 1939-1940 was 196; graduates 39. The next session begins Oct. 1, 1940, and ends May 27, 1941. The Dean is Edward L. Turner, M.D.

VANERBILT UNIVERSITY SCHOOL OF MEDICINE, Twenty-First Street at Edgehill.—This school was founded in 1874. The first class graduated in 1875. Coeducational since September 1925. The faculty numbers 239. For matriculation, students must be graduates of collegiate institutions of recognized standing or seniors in absentia, who will receive the bachelor degree from their college after having completed successfully at least one year of work in the school of medicine. The course covers four years of nearly nine months each. The total fees are, respectively, \$415, \$415, \$415 and \$420. The registration for 1939-1940 was 200; graduates, 54. The next session begins Sept. 23, 1940, and ends June 11, 1941. The Dean is Walter S. Leathers, M.D.

TEXAS

Dallas

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 810 College Avenue.—Organized in 1900 as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. Coeducational since organization. The first class graduated in 1901. The faculty consists of 113 professors and 103 instructors and assistants, a total of 216. Entrance requirements are three years of collegiate work. The course covers four years of eight months each. The fees are, respectively, \$414, \$404, \$399 and \$424. The registration for 1939-1940 was 305; graduates, 75. The next session begins Sept. 30, 1940, and ends June 2, 1941. The Dean is W. H. Moursund, M.D.

Galveston

UNIVERSITY OF TEXAS SCHOOL OF MEDICINE, 912 Avenue B.—Organized in 1891. The first class graduated in 1892. Coeducational since organization. It has a faculty of 45 professors and 53 instructors and lec-

turers, a total of 98. The curriculum covers four years of eight months each. The entrance requirement is three years of collegiate work. The total fees are, respectively, \$88, \$92, \$100 and \$102. There is a matriculation fee of \$50 for each year. The registration for 1939-1940 was 374; graduates, 90. The next session begins Oct. 1, 1940, and ends May 31, 1941. The Dean is John W. Spies, M.D.

VERMONT

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park.—Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. It has a faculty of 61 professors and 53 instructors, and assistants, a total of 114. Three years of collegiate work are required for admission. The course of study covers four years of nine months each. For residents of Vermont the tuition fee is \$300 each session. Nonresidents are charged an additional \$150 each session. A \$25 fee is charged for the doctor's degree. The registration for 1939-1940 was 131; graduates, 36. The next session begins Sept. 18, 1940, and ends June 16, 1941. The Dean is Hardy A. Kemp, M.D.

VIRGINIA

Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. It has a faculty of 46 professors and 40 lecturers, instructors, assistants and others, a total of 86. Three years of college work are required for admission. For residents of Virginia the total fees are, respectively, \$419, \$401, \$366 and \$366. Nonresidents are charged an additional \$50 each year. The registration for 1939-1940 was 254; graduates, 62. The next session begins Sept. 12, 1940, and ends June 9, 1941. The Dean is Harvey Ernest Jordan, Ph.D.

Richmond

MEDICAL COLLEGE OF VIRGINIA, Twelfth and Marshall Streets.—Organized in 1838 as the Medical Department of Hampden Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. In 1914 the North Carolina Medical College was merged. Coeducational since 1918. Classes were graduated in 1839 and in all subsequent years. It has a faculty of 80 professors and 126 lecturers, instructors and others, a total of 206. Three years of collegiate work are required for admission. The course covers four years of eight and one-half months each. Total fees are, respectively, \$344, \$344, \$329 and \$361. Nonresidents are charged an additional \$125 each year. The registration for 1939-1940 was 295; graduates, 66. The next session begins Sept. 3, 1940, for the first year class; Sept. 16, 1940, for all other classes, and ends June 3, 1941. The Dean is Lee E. Sutton Jr., M.D.

WISCONSIN

Madison

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL, 408 North Charter Street.—Organized in 1907. Gave only the first two years of the medical course until 1925, when the clinical years were added. Coeducational since organization. Three years of collegiate work are required for admission. The B.S. degree in medical science is conferred at the end of the first year. It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131. The fees are, respectively, \$222, \$212, \$182 and \$120. An additional fee of \$200 each year is charged nonresidents. The registration for 1939-1940 was 262; graduates 48. The next session begins Sept. 25, 1940, and ends June 23, 1941. The Dean is William S. Middleton, M.D.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE, 561 North Fifteenth Street.—Organized in December 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. It has a faculty of 178. Three years of collegiate work are required for admission. The curriculum covers four years of eight and a half months each, and one year's internship in an approved hospital. The fees are as follows: first year, \$462; second year, \$450; third year, \$450; fourth year, \$400. The registration for 1939-1940 was 313; graduates, 72. The next session begins Sept. 30, 1940, and ends June 11, 1941. The Dean is Eben J. Carey, M.D.

CANADA

Alberta

UNIVERSITY OF ALBERTA FACULTY OF MEDICINE, Edmonton.—Organized in 1913. Coeducational since organization. Has given the complete six-year medical course since 1924. The faculty includes 23 full time and 45 part time professors, instructors, assistants and others, a total of 68. Tuition for the first year is \$150, for the second, third and fourth years \$215, for the fifth and sixth years \$225. The registration for 1939-1940 was 253; graduates, 35. The next session begins Sept. 24, 1940, and ends May 13, 1941. The Acting Dean is John James Ower, M.D.

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE, Bannatyne Avenue, Winnipeg. Organized in 1883 as Manitoba Medical College; first class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 26 professors and 80 instructors and assistants, total of 106. Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university. The course extends over four years of eight months each and a hospital internship. The total fees are, respectively, \$298, \$293, \$293, \$293, \$77. The registration for 1939-1940 was 218; graduates, 45. The next session begins Sept. 20, 1940, and ends May 14, 1941. The Dean is A. T. Mathers, M.D.

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE, Morris Street, Halifax.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. It has a faculty of 34 professors and 34 demonstrators, lecturers and others, a total of 68. Requires for matriculation two years of arts. The medical course covers four years and a hospital internship of one year. The fees are \$317, \$322, \$317, \$307 and \$307 for each year, respectively; \$250 additional registration fee payable by students outside the British Empire. The registration for 1939-1940 was 183; graduates, 35. The next session begins Sept. 10, 1940, and ends May 13, 1941. The Dean is H. G. Grant, M.D.

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 60. The fee for the first year is \$233 and \$255 for each of the other five years. The course covers six years of thirty teaching weeks each. The registration for 1939-1940 was 278; graduates, 62. The next session begins Sept. 26, 1940, and ends May 16, 1941. The Dean is Frederick Etherington, M.D.

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL, Ottawa Avenue, London.—Organized in 1881 as the Western University Faculty of Medicine; first class graduated in 1883, and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 88. The course of study covers six years of eight months each. The total fees to residents of Canada for the last four years, respectively, are \$291, \$287, \$295 and \$295; nonresidents are charged \$516, \$512, \$520 and \$520 for each of the last four years. The registration for 1939-1940 was 223; graduates, 31. The next session begins Sept. 16, 1940, and ends May 17, 1941. The Dean is F. J. H. Campbell, M.D.

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto.—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department, and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The course of study covers six years of eight months each. The B.Sc. (Med.) degree is conferred at the end of the third or sixth year. It has a faculty of 74 professors and 348 lecturers, associates and others, a total of 422. The fees are \$226 for the first year; for the second, \$389; \$296 for the third year, \$321 for the fourth and fifth years, and \$353 for the sixth year. The registration for 1939-1940 was 777; graduates, 138. The next session begins Sept. 24, 1940, and ends May 17, 1941. The Dean is W. E. Gallie, M.D.

Quebec

LAVAL UNIVERSITY FACULTY OF MEDICINE, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine; first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 81. The fees for each of the medical years are \$175 for residents of Canada. Nonresidents are charged an extra fee of \$175 each year. The premedical requirement is a B.A. degree or its equivalent. The registration for 1939-1940 was 314; graduates, 51. The next session begins Sept. 11, 1940, and ends May 30, 1941. The Secretary General of the University is Rev. Aimé Labrie.

MCGILL UNIVERSITY FACULTY OF MEDICINE, 3640 University Street, Montreal.—Founded in 1823 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-1839, owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1919. Three years of collegiate work are required for admission. The M.D. is conferred upon the completion of four sessions of 36 teaching weeks. Graduates are not eligible for licensure until they have satisfactorily completed one year of internship in an approved hospital. The faculty consists of 59 professors and 156 lecturers and others, a total of 215. The total fees for each of the four medical years are \$391 plus \$100 for non-British subjects. The registration for 1939-1940 was 444; graduates, 161. The

next session begins Sept. 4, 1940, and ends May 31, 1941. The Dean is J. C. Simpson, LL.D.

UNIVERSITY OF MONTREAL, FACULTY OF MEDICINE, 1265 St. Denis Street, Montreal.—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891, by Act of Parliament, the Medical Faculty of Laval University (organized in 1878) was absorbed. Present name by Act of Parliament in 1920. A class was graduated in 1843 and each subse-

quent year. Coeducational since 1925. The faculty numbers 135. The B.A. or B.S. degree, or its equivalent, is a prerequisite to the premedical year, which precedes a five year medical course, the fifth year being a compulsory internship year. The total fees for each of the five years respectively are \$245, \$229, \$271, \$235, \$218. The registration for 1939-1940 was 205; graduates 48. The next session begins Sept. 15, 1940, and ends June 15, 1941. The Dean is Albert LeSage, M.D.

DESCRIPTION OF SCHOOLS OF THE BASIC MEDICAL SCIENCES

ALABAMA

University (Tuscaloosa)

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE.—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868, inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907, when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. Coeducational since 1920. Minimum entrance requirements are three years of collegiate work. The course of study covers two years of thirty-six weeks each. The faculty includes 15 professors and 12 instructors, assistants, and others, a total of 27. The tuition fees are \$271 each year. Each class is limited to fifty students. The registration for 1939-1940 was 103. The next session begins Sept. 11, 1940, and ends May 27, 1941. The Dean is Stuart Graves, M.D.

MISSISSIPPI

University

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE.—Organized in 1903. Coeducational since organization. Gives only the first two years of the medical course. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. The session extends over eight and one-half months. Entrance requirement is three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The faculty includes 8 professors, 2 assistant professors, 1 associate professor, 1 adjunct professor, 20 instructors, assistants and others, a total of 32. The total fees for the first year are \$353, and for the second year \$325. The nonresident fee is \$50 additional each year. The registration for 1939-1940 was 44. The next session begins Sept. 16, 1940, and ends June 2, 1941. The Dean is B. S. Guyton, M.D.

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE.—Organized at St. Louis in 1845; was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. The faculty includes 21 professors and 14 instructors, lecturers and others, a total of 35. The entrance requirements are 90 semester hours of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. Total fees for the first year are \$191, for the second, \$170. The registration for 1939-1940 was 75. The next session begins Sept. 16, 1940, and ends June 13, 1941. The Dean is Dudley S. Conley, M.D.

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL.—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Courses of the third and fourth year were discontinued in 1914. The faculty consists of 21 professors and 11 instructors, a total of 32. Three years of collegiate work and candidacy for the bachelor's degree are required for admission. The course covers nine calendar months in each year, or eight months of actual teaching. Candidates for the A.B. degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department. The tuition is \$450 for each year. The registration for 1939-1940 was 42. The next session begins Sept. 19, 1940, and ends June 13, 1941. The Dean is John P. Bowler, M.D.

NORTH CAROLINA

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Coeducational since 1914. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the first year. The faculty is composed of 15 professors and 9 instructors, a total of 24. The fees for each year are \$300 for residents; nonresidents, an additional fee of \$100. The registration for 1939-1940 was 79. The next session begins Sept. 24, 1940, and ends June 8, 1941. The Acting Dean is W. Reese Berryhill, M.D.

Wake Forest

WAKE FOREST COLLEGE SCHOOL OF MEDICAL SCIENCES.—Organized in 1902. The faculty numbers 16 professors, and 29 assistant professors, instructors, assistants and lecturers, making a total of 45. Only the first

two years of the medical course is offered. On Aug. 4, 1939, the Board of Trustees accepted the resources of the Bowman Gray Foundation in Winston-Salem and authorized the school to be moved to that city and expanded to offer instruction to include the entire four years leading to the M.D. degree. The physical plant is now under construction. The date of the beginning of the clinical years has not been announced. Ninety semester hours of collegiate work are required for admission. The B.S. degree is given after the completion of the first year in the School of Medical Sciences. Each annual course extends over nine months. Tuition for each year is \$300. The registration for 1939-1940 was 60. The next session begins Sept. 10, 1940, and ends June 2, 1941. The Dean is C. C. Carpenter, M.D.

NORTH DAKOTA

Grand Forks

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE.—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years' work in a college of liberal arts is required for admission. The B.S. degree in combined arts-medical course is conferred at the end of the second year. The faculty consists of 8 professors and 8 instructors, a total of 16. The fees are \$80 each year for resident students and \$165 for nonresidents. The registration for 1939-1940 was 49. The next session begins Sept. 16, 1940, and ends June 10, 1941. The Dean is H. E. French, M.D.

SOUTH DAKOTA

Vermillion

UNIVERSITY OF SOUTH DAKOTA SCHOOL OF MEDICAL SCIENCES.—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1937. Coeducational since organization. Offers only the first two years of the medical course. Three years' work in a college of liberal arts is required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to the A.B. degree. The B.S. degree is conferred at the end of the second year on those students who do not hold a previous Bachelor's degree. The faculty numbers 18. The tuition is \$150 each year for residents and \$250 for nonresidents. The registration for 1939-1940 was 50. The next session begins Sept. 18, 1940, and ends June 9, 1941. The Dean is Joseph C. Ohlmacher, M.D.

UTAH

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE, University Street.—Organized in 1906. Coeducational since organization. Gives only first two years of medical course. Each school year covers thirty-six weeks. Three years of collegiate work are required for admission. The medical faculty consists of 11 professors, 2 instructors, 20 lecturers and demonstrators, and 5 fellows, assistants, and technicians, a total of 38. The fees for each year are \$229. There is a nonresident fee of \$25 for each quarter. The registration for 1939-1940 was 56. The next session begins Sept. 23, 1940, and ends May 31, 1941. The Dean is L. L. Daines, M.D.

WEST VIRGINIA

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1902, gives the first two years of the medical course. Coeducational since organization. Three years of collegiate work are required for admission. The B. S. degree in medicine is conferred at the end of the second year. Session extends through nine months. Faculty numbers 24. Fees for residents of the state are, respectively, \$254 and \$264; nonresidents, \$150 additional each year. The registration for 1939-1940 was 45. The next session begins Sept. 17, 1940, and ends June 7, 1941. The Dean is Edward J. Van Lierc, M.D.

CANADA

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES, Saskatoon.—Organized in 1926. Coeducational. Offers the first two years of the medical course. Students require three more years of medicine for graduation. Two years of collegiate work are required for admission. The B.A. degree is conferred at the end of the second year. The medical faculty includes 7 professors and 4 lecturers and assistants, a total of 11. The fees are \$150 for each year. The registration for 1939-1940 was 43. The next session begins Sept. 23, 1940, and ends May 9, 1941. The Dean is W. S. Lindsay, M.B.

GRADUATE MEDICAL EDUCATION

Continuation Study for Practicing Physicians in the United States, 1939-1940

During a period of two years, beginning in October 1937, forty-six states and the District of Columbia were visited by a representative of the Council on Medical Education and Hospitals for the collection of data on the facilities available and programs in effect throughout the country for the continuing education of practicing physicians. The two states not visited were Delaware and Nevada. Progress reports on graduate activities of medical societies, medical schools, hospitals and other educational institutions appeared in the Educational Numbers of *THE JOURNAL* of 1938¹ and 1939.² A review of the Association's interest in graduate medical education since 1913 was published in composite form by the Council in May 1940.³

Presented herewith is a report on similar opportunities for continuation study offered during the fiscal year July 1, 1939, to July 1, 1940. The data which form the basis of this presentation were obtained by correspondence and questionnaire.

ORGANIZATION AND ADMINISTRATION

Opportunities for practicing physicians to engage in continuation study are outlined in tables 1-A, pages 710-712, and 1-B, pages 714-719, and table 2, pages 721-724. Courses reported in table 1-A were of an itinerant character, in that the instruction was taken to the physician in or near his local community. Centers listed in table 1-B provided ample facilities for clinical instruction. With certain exceptions, in the first type of course the instructor does most of the traveling, while in the latter the physician desiring continuation study frequently travels to the center where clinical teaching may be emphasized over longer periods. There were reported 129 programs for continuation study in forty-one states and the District of Columbia, including four states which made provision for such opportunities outside their states.

Forty-one itinerant programs of continuation study for practicing physicians were offered in or near the home communities of physicians in thirty-one states. Thirty-one of the courses offered were sponsored either singly or jointly by state medical societies. State boards of health sponsored twenty-two. Extension divisions of universities and medical schools sponsored four courses each. Of these forty-one itinerant study courses, twenty were directed by state medical societies, twelve by state boards of health, five by extension divisions of universities and four by tuberculosis organizations.

Continuation study in centers where there are ample facilities for clinical instruction is outlined in table 1-B, in which are listed eighty-eight courses offered in thirty-one states and the District of Columbia. Four other states provided opportunity for physicians to continue professional study elsewhere. Fifty-two courses were sponsored by medical schools, including six graduate and postgraduate schools, twenty-four by medical and clinical societies and academies of medicine, fifteen by departments of health, three by the Commonwealth Fund of New York and the Bingham Associates Fund, eight by hospitals, three by a university center for continuation study, three by universities not having medical departments and one each by a university extension division and an institute of technology.

Medical school graduate programs were usually directed by the dean of the school, although sometimes the professor in charge of the course, the chairman of a postgraduate committee or of a department of postgraduate education in the medical school or the director of the division of graduate study would act. Courses sponsored by medical societies were generally directed by committee chairmen.

METHODS OF INSTRUCTION

States which provided opportunities for physicians to continue professional study near their home communities offered general subjects of medicine in sixteen courses, obstetrics and gynecology in fifteen, pediatrics in fifteen, general and traumatic surgery in five and special subjects in thirteen.

Instruction was given for four or more days, in succession or intermittently, in twenty-one of these itinerant courses. Clinics, symposiums or conferences, in addition to lectures, were included in thirty-six courses. Local hospitals were utilized in thirty of the forty-one programs. Whenever hospitals were not suitable or available, public buildings, hotels, halls, club rooms and other local facilities were used. Approximately one half of the instructors engaged as field clinicians came from within the state where continuation study was offered, and in approximately one half of the courses out of state physicians participated. Of the total, three fourths of the instructors were from medical schools.

Where continuation study featured clinical instruction at one center, such subjects as general medicine, obstetrics, pediatrics and surgery were included. All but ten of the graduate programs of longer duration emphasized clinical instruction. Opportunities were given for continuing study of special as well as general subjects of medicine, including allergy, anesthesia, broncho-esophagology, cardiology, electrocardiography, endocrinology, forensic medicine, genito-urinary surgery, gastroscopy, gynecology, hematology, industrial medicine, laboratory procedures, metabolism, ophthalmology, otolaryngology, physical therapy, psychiatry, public health, radiology, tuberculosis, urology and venereal diseases. Other special courses were available at thirteen medical schools and universities. Forty-three medical schools participated in postgraduate programs in medical centers. In only ten centers was instruction in preclinical subjects offered.

The duration of clinical study varied from five days to one year. Forty-seven of the eighty-eight courses reported lasted from five days to three weeks. Twenty-three programs were conducted over periods of four weeks or more. Thirteen courses fell within both categories and five others were of variable duration. The time of year in which instruction was given varied considerably. In some of the medical schools it was found necessary to accept physicians for short terms of graduate study during vacation periods in order to accommodate them when undergraduate students were not in attendance.

Something more than didactic lectures was included in the courses given with a few exceptions. Laboratory demonstrations, clinics, ward rounds, round table discussions, clinical pathologic and other conferences, symposiums and bedside teaching as well as other practical

(Continued from page 709)

clinical demonstrations were attempted. Laboratory as well as clinical facilities were utilized. In addition to medical schools which opened their facilities to practicing physicians for short periods of clinical study, use was made of hospitals, medical society buildings, outpatient clinics, health agencies and, in two instances, hotels.

REGISTRATION

All continuation courses were open to licensed physicians practicing in or near the community in which the instruction was given. In some only practicing physicians were admitted to the course and, in fifteen of the forty-one itinerant opportunities, membership in county or state medical societies was required. Registration varied from fifteen at each session in one instance to a total of 2,867 in one state. The median number of practicing physicians who enrolled for these courses of continuation study was 390.

Eligibility for admission to courses featuring clinical instruction included a doctor of medicine degree in every instance and additional qualifications in some. The yearly attendance varied appreciably; 500 or more physicians were accommodated in seven centers, from 200 to 500 in eight, from 100 to 200 in eight others, while less than 100 were in attendance in the remaining courses listed. Where large numbers of physicians were accommodated, either many varied courses with limited attendance were scheduled, like those offered at Columbia University in New York City, or the instruction simulated that given in clinical conferences, such as the annual program of the Philadelphia County Medical Society.

FINANCIAL SUPPORT

For thirty of the forty-one itinerant continuation courses no registration fees were charged; in ten, fees varied from \$2.50 to \$15. Thirty-one state medical societies contributed materially and financially. State boards of health aided in the support of twenty-seven courses; federal agencies contributed to the support of ten and universities, including medical and graduate schools and extension divisions, twelve. The Commonwealth Fund has given financial aid for promoting graduate study in four states, and tuberculosis associations of four states gave financial support.

With nineteen exceptions, continuation courses featuring clinical material at one center required fees of from \$5 to \$1,000. Medical schools most frequently were the contributing agencies, with medical societies, state departments of health and private foundations and funds sharing part of the expenses of clinical instruction. Sixteen courses received financial support from federal agencies. In all but two cases this aid was supplied by state boards of health to medical schools. Through the financial assistance of the Bingham Associates Fund, physicians of Maine traveled to Boston for continuation study. Similarly, through the aid of the state health department, physicians from Utah enrolled in courses offered by the University of California. Federal funds supplied to health departments in Minnesota, North Dakota and South Dakota were used to pay the expenses of physicians taking courses at the Center for Continuation Study connected with the University of Minnesota.

CLINICAL CONFERENCES, GRADUATE ASSEMBLIES AND STUDY COURSES

Information was received regarding fifty-seven clinical conferences, graduate assemblies and study courses. These data are summarized in table 2, page 721. Such

opportunities were provided for practicing physicians in thirty-two states and the District of Columbia by state and county medical societies, clinical societies, medical schools and health departments. Forty-four of the programs were sponsored by medical and clinical societies, some in cooperation with other organizations and ten by medical schools, either independently or jointly with medical societies, departments of health or hospitals.

Clinical conferences, with a few exceptions, were of from one to four days' duration and usually held in the spring or fall in metropolitan areas with facilities to accommodate large assemblies. Lectures were given in all but two programs. In more than half of these conferences, clinics as well as round table discussions and demonstrations were conducted.

About one half of the conferences were concerned with general discussions in medicine and surgery and the remainder with such subjects as obstetrics, pediatrics, heart disease, endocrinology, tuberculosis, venereal disease and pneumonia. In forty-one of the fifty-seven programs given, the facilities of hospitals and medical schools were used. Medical school instructors were engaged for forty-four of the programs. Physicians not in teaching positions but from within the state in which the clinical conference was held participated in thirty-one programs, and out of state speakers were engaged in thirty-six.

Practicing physicians were eligible for admission to all conferences and in eleven membership in county, state or special medical societies was required. In all but twenty-six programs, registration fees varied from \$1 to \$30. The approximate yearly attendance at clinical conferences ranged from seven to 1,015, the median being 117.

Forty-four programs were supported either in whole or in part by medical, clinical or special societies. Twenty-three were independent efforts on the part of these societies. City and state departments of health contributed to the support of fourteen courses. Two of these were sponsored and financed by health departments alone. Medical schools, universities or colleges aided in the support of eighteen conferences and assemblies. There were three independent efforts by one or more of the agencies just named. Federal and state agencies, hospitals and private funds aided financially eighteen programs.

SUMMARY

1. Forty-one states and the District of Columbia provided a form of continuation study for physicians and, when clinical conferences were included, forty-four states and the District of Columbia offered graduate opportunities. Delaware, Nevada and New Mexico reported no programs.

2. Forty-one itinerant courses of continuation study for practicing physicians were offered in or near the home communities of physicians in thirty-one states. State medical societies sponsored the majority, with state boards of health as well as extension divisions of universities and medical schools as joint sponsors in many states. Medical schools sponsored most of the eighty-eight opportunities where clinical instruction might be featured at one center over five or more days in thirty-one states and the District of Columbia. Five states including Utah provided for such study outside the state.

3. According to reports received, the approximate attendance at courses of an itinerant nature, clinical

1. Courses accepted as part of the five year study requisite for certification by the American Board of Psychiatry and Neurology.

2. Negro students compose a majority of those in attendance.

3. Courses offered especially for Fellows of the College or for those preparing either to meet requirements for membership in the College or certification by the American Board of Internal Medicine.

(Continued from page 713)

courses and graduate assemblies totaled 52,012. The individual registration of these groups in the order named was 20,213, 15,399 and 16,400.

4. Medicine, surgery, obstetrics, pediatrics and special subjects were included in the graduate instruction given. Instruction featuring clinical material included laboratory demonstrations, clinics, ward rounds, round table discussions, clinical pathologic and other conferences, symposiums and bedside teaching, as well as other practical clinical demonstrations.

5. Out of state instructors participated as frequently as physicians of the same state. Medical school faculties contributed half of the instructors to itinerant courses and conducted most of the instruction in which clinical material was featured over five or more days.

6. Registration fees were charged infrequently for itinerant courses but in no course did amounts exceed \$15. For graduate programs stressing clinical instruction at one center, fees ranged from \$5 to \$1,000.

FOUNDATIONS

Eight foundations contributed financial aid directly or indirectly for the support of postgraduate courses.

Bingham Associates Fund.—In 1937, through the generosity of William Bingham II, the New England Medical Center in Boston was created for rural physicians of New England to pursue postgraduate study at no expense. This fund makes possible fellowships for a month's work in general medicine with a stipend of \$250. Reports to date indicate that these opportunities have been taken advantage of only by Maine physicians, forty-eight having enrolled for the 1939-1940 courses.

Commonwealth Fund of New York.—The Commonwealth Fund gives assistance in extension medical education through grants-in-aid to specific projects and also offers fellowships to practicing physicians in connection with rural hospital and public health programs. Fellowships are provided in Boston hospitals for one month in medicine, pediatrics, obstetrics and office surgery. The stipend is \$250 plus tuition and travel expenses. It was reported that twenty-five men took advantage of these fellowships during 1939-1940. This fund provides similar opportunities for physicians in areas throughout the country where there is need for better medical facilities and a higher standard of medical practice.

Mayo Foundation for Medical Education and Research.—Neither the Mayo Clinic nor the Mayo Foundation offers short courses of any kind. However, lectures are concentrated in the fall and winter quarters with a few during the spring and are arranged in such a way that over a three year period a rather general survey of all fields in which training is offered is made by members of the staff. These lectures are planned to coordinate the basic sciences with the clinical fields and are open to visiting physicians. Also about twice a year a series of lectures and demonstrations in some one field is given for a period of one week. There is no charge for this and no arrangements need be made in advance.

W. K. Kellogg Foundation.—Fifteen courses were financed on a fellowship basis whereby the W. K. Kellogg Foundation contributed to physicians the cost of transportation, tuition and approximately \$25 a week for other expenses. The maximum contribution to any one physician on any course was \$150. During 1939-1940 such subjects as anemias, pneumonia, pediatrics, electrocardiography, ophthalmology, internal medicine, general surgery, x-ray diagnosis, otolaryngology and

gynecology were given during periods of from four days to seven weeks. These courses were conducted at the Universities of Michigan, Buffalo, Rochester, Tulane and Harvard and several other locations. Forty-seven physicians took advantage of these opportunities.

Other Foundations.—The Rockefeller Foundation, the Rackham Fund, the Rosenwald Fund, the Edward L. Trudeau Foundation and the Lillia Babbitt Hyde Foundation are organizations which have contributed financial aid, in amounts varying from approximately \$500 to \$45,000, directly to agencies such as medical schools, universities or associations for the purpose of sponsoring continuation study courses for practicing physicians.

OPPORTUNITIES FOR NEGRO PHYSICIANS

Alabama, the District of Columbia, Georgia, Louisiana, Missouri, Tennessee, Virginia, Florida, North Carolina, Pennsylvania and Texas offered courses for Negro physicians, details of which are referred to in tables 1-B, pages 714-719, and 2, pages 721-724. Organizations participating in these courses included state departments of health, medical schools, miscellaneous medical societies, hospitals, universities, federal agencies and private funds. Instruction was offered in medicine, surgery, obstetrics, pediatrics, tuberculosis, venereal diseases, diseases of nutrition, abdomen and chest. Courses varied in length from three days to three months, the majority being given in the spring or summer. Clinical instruction was given in all but one course. Attendance ranged from eleven to 204, the median being thirty-two. Fees were from \$5 to \$20 except in four instances, in which no fees were charged. Separate teaching centers have been established at Memphis and Nashville, Tenn., and clinics and courses given which are attended regularly. Postgraduate institutes for Negro physicians, sponsored by local Negro, medical and tuberculosis associations, were held last spring in St. Louis and Pittsburgh.

SCIENTIFIC ASSOCIATIONS

A total of 208 organizations holding scientific sessions of value to practicing physicians during 1939-1940 were noted. Not the least of these was the annual scientific program of the American Medical Association. Ninety-three of these agencies were national in origin, forty-five interstate, forty-nine district and twenty-one metropolitan. Methods of presentation included lectures, clinics, demonstrations, conferences, symposiums and discussions. The sessions varied in length from one to six days and covered all the specialties.

MISCELLANEOUS ACTIVITIES

In order to meet the individual needs of each state in providing continuation study for practicing physicians, medical and special societies, state departments and medical schools have attempted to provide different types of instruction in various states where it is not always possible for the practicing physician to attend organized courses such as those mentioned in the foregoing tables.

The Colorado State Medical Society has made an effort to bring opportunities in postgraduate study to its local physicians by sponsoring symposium programs on venereal disease, cancer control, tuberculosis control, and other subjects before component societies annually at the convenience of each component.

(Continued from page 720)

In Connecticut the state department of health has cooperated with the state medical society by presenting to thirteen local medical societies a one evening meeting devoted to pneumonia. The health department paid an honorarium to secure an outside speaker. The total attendance at these lectures was 859.

The Kentucky State Board of Health has held a number of conferences before local medical societies at which two pediatricians have presented papers, held clinics and made talks on general health measures before professional and lay audiences.

During the past two years the Massachusetts Medical Society, in cooperation with the state health department, the United States Public Health Service and the United States Children's Bureau, conducted teaching clinics in gonorrhea and syphilis. Student physicians attended 150 such clinics at the Boston Dispensary and the Massachusetts General Hospital Syphilis Clinic. Registration was free. Any legally registered physician in Massachusetts was eligible to attend.

Facilities of the University of North Dakota School of Medicine were available to physicians for special work such as anatomic dissection or experimental work in physiology, pathology, dietetics and surgery. Time spent varied from a few hours or a day to a week or several months or a year. Charges were nominal and represented only cost of materials used.

The Division of Venereal Disease Control of the Oregon State Board of Health cooperated with the Committee of the Oregon State Medical Society by providing, on request, speakers on syphilis or gonorrhea for meetings of local medical societies or hospital staffs. Speakers in five instances were from the department of dermatology and syphilology of the universities of Oregon and California and the department of urology of the University of Oregon and in two instances from the Division of Venereal Disease Control. These speakers were provided to local societies through the use of federal funds.

In Rhode Island a group of five members of the American Academy of Pediatrics have taken over one meeting of each district society during the year for a panel discussion on preventive inoculations. Each member of the panel is paid \$25 for each meeting.

A similar activity has been carried on in Utah under the sponsorship of the Utah Academy of Pediatrics. On request of a component medical society, three pediatricians go to one of the society's regular meetings to hold discussions. This is done on a panel or round table basis. The academy members give their time, and the state board of health pays the expense of the trip, which averages from \$25 to \$50, depending on the distance covered. The same service is offered by Utah obstetricians.

Another effort of the Division of Maternal and Child Health of the Utah State Board of Health was the employment of a consultant in obstetrics and one in pediatrics to act in a teaching and consultative capacity. Briefly, the duties of the obstetrician were to visit maternal health conferences, to give case consultation service in rural areas, and individual or group instruction in obstetrics to rural physicians, to assist in staff education programs in certain phases of clinical obstetrics and to conduct a study of heart disease as a complicating factor in maternal morbidity and mortality in Utah. His activities were almost entirely on an

individual basis and he worked with approximately ninety physicians. The pediatrician gave discussions before medical society groups and hospital staff meetings and gave individual consultations on request.

In Virginia the state medical society and the state department of health annually sponsor chest x-ray conferences at medical society meetings.

The sum of approximately \$2,500 was budgeted by the Wyoming State Department of Health for post-graduate instruction. This service provides speakers for local medical society scientific programs in obstetrics, pediatrics and orthopedics. The funds for financing this instruction were made available through the Social Security Board.

PRINCIPLES REGARDING GRADUATE MEDICAL SCHOOLS

Approved by the House of Delegates of the American Medical Association, June 1923

(Revised June 11, 1940)

I. Organization

A graduate medical school should be incorporated as a non-profit institution. Its board of trustees should be composed of public spirited men or women having no financial interest in the operations of the school or its associated hospitals. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, that should be clearly stated. Officers and faculty of the school should be appointed by the board.

II. Administration

There should be careful and intelligent supervision of the school by a dean or other executive officer who holds and has sufficient authority to carry out the ideals of present day graduate medical education.

The graduate school shall maintain a full and accurate record of each student's qualifications:

- (a) medical degree and licensure,
- (b) internship or equivalent training,
- (c) residency or equivalent training,
- (d) attendance in school,
- (e) proficiency as appraised by
 - (1) medical contributions,
 - (2) research,
 - (3) membership in county medical society or other scientific bodies,
 - (4) examination,
 - (5) qualifying opinion by student's teachers.

In the case of study for a specialty, a full record of the prescribed course and duration of study with attendance and final estimate of proficiency should be made.

The graduate school should publish an annual announcement and bulletins or catalogues giving detailed information in regard to its courses of instruction, its teachers and details of the laboratories, dispensaries and hospital patients. It should outline the various opportunities for study offered in both fundamental and clinical branches and a list of those to whom advanced degrees or certificates were granted.

III. Faculty

The graduate medical school should have a faculty well trained in and responsible for instruction in all subjects in which courses for study are announced, including the essential review and advanced work in the preclinical sciences. This faculty should be organized under competent department heads.

IV. Laboratories

The school should possess well equipped laboratories. The postmortem rate shall be in conformity to the rules for approved hospitals.

V. Clinical Facilities

The graduate medical school should have control of a teaching hospital with adequate outpatient clinic. It should have sufficient material to enable it to provide satisfactory clinical study in the fields of medicine in which courses are offered, so that students may personally examine patients in the hospital wards and in the dispensary and make the essential laboratory examinations.

VI. Library

The graduate school should have a medical library under the supervision of a competent librarian and staff. It should include text and reference books, and bound medical periodicals and the essential indexes. For any library, the *Quarterly Cumulative Index Medicus* is essential. It should receive regularly the more important medical periodicals, the latest numbers of which are easily accessible.

The school should maintain adequate museum facilities, especially in anatomy and pathology.

VII. Resources

Experience has shown that it is not possible to maintain high educational standards on income from student fees alone. Other sources of financial support are deemed essential for the proper conduct of graduate medical schools and should be listed in the annual announcement.

VIII. Requirements for Admission

(a) A physician who does not intend to limit his practice to a specialty shall present satisfactory evidence that he is a graduate of a medical school and that he is licensed to practice in the state in which he resides.

(b) The physician who desires to prepare himself to specialize, or who has limited his practice to a specialty, shall present satisfactory evidence that he is a graduate of a medical school approved by the Council on Medical Education and Hospitals and that he has completed at least one year's internship in a hospital approved by the Council or the equivalent.

IX. Curriculum

The graduate school should have its various courses designed to prepare the physician for the practice of a specialty so graded that the student, if he desires, may follow a progressive and systematic program of two or more years' duration. If at some previous time, or in other institutions, the student has satisfactorily completed certain portions of the work, he may be given credit for the same, with a proportional advanced standing. Institutions offering courses leading to restricted practice in a specialty should provide:

- (a) courses in anatomy, pathology, chemistry and the other basic preclinical sciences which apply to the respective specialties;
- (b) clinics in which students personally examine patients in hospital wards and outpatient departments and follow these patients throughout their illness;
- (c) courses of operative and laboratory—cadaver—technic appropriate to each specialty, and
- (d) for those especially qualified, opportunity for research work with proper critical supervision should be provided.

Short operative courses offered in any of the clinical specialties should include a full review with diagnostic and clinical courses so arranged that they become integral parts of a complete program.

X. Advanced Degrees and Certificates

No advanced degree or certificate should be granted to any one who has not demonstrated by examination or otherwise proficiency in his specialty, nor to any one who has not completed at least one academic year in full time study in the institution granting the certificate.

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES

The announcements of approved examining boards in medical specialties are reproduced herewith.

AMERICAN BOARD OF ANESTHESIOLOGY, Inc.
AN AFFILIATE OF THE AMERICAN BOARD
OF SURGERY

RALPH M. WATERS, President, Madison, Wis.
HENRY S. RUTH, Vice President (Liaison Officer to the American Board of Surgery), Merion, Pa.
PAUL M. WOOD, Secretary-Treasurer, 745 Fifth Avenue, New York.
JOHN S. LUNDY, Rochester, Minn.
E. A. ROVENSTINE, New York.
H. BOYD STEWART, Tulsa, Okla.
RALPH M. TOVELL, Hartford, Conn.
PHILIP D. WOODBRIDGE, Boston.
CHARLES F. MCCUSKEY, Glendale, Calif.

HISTORY

The plan for this organization was devised to conform with those of other examining boards in medical specialties, by a committee representing the American Society of Anesthetists, Inc., the American Society of Regional Anesthesia, Inc., and the Section on Surgery of the American Medical Association. These organizations adopted the tentative plans submitted, and the formation of the American Board of Anesthesiology, Inc., an affiliate of the American Board of Surgery, Inc., was completed on June 2, 1937. The Advisory Board for Medical Specialties, and the Council on Medical Education and Hospitals of the American Medical Association approved the affiliation in 1938. Diplomates of this Board will be designated "A.B. 13" in the Directory and Biographical Departments of the American Medical Association.

PERSONNEL

The members of the examining board were elected by the American Society of Regional Anesthesia, Inc., the American Society of Anesthetists, Inc., and the Section on Surgery of the American Medical Association. Each cooperating society has three representatives, thus giving national and regional representation in the composition of the board.

The term of membership is for six years. Each cooperating association has the appointing power of its representatives subject to the approval of the board.

PURPOSES

1. To establish criteria of fitness to be designated a specialist in the practice of anesthesiology.

2. To improve educational facilities and practice in medical schools and hospitals, and furnish lists of these, together with lists of individual instructors who give adequate instruction and training in anesthesiology.

3. To arrange, control, and conduct examinations to determine the qualifications, and grant a certificate to those who voluntarily apply and meet the required standards. Such certification will serve to provide the public and the professions with the opportunity to select the best available service.

(Conferring of degrees is a prerogative of the universities, and the Board of Anesthesiology makes no attempt to grant degrees, regulate or control the practice of anesthesiology in any way whatsoever, by license or restriction.)

QUALIFICATIONS FOR ELIGIBILITY TO CERTIFICATION

A. *General*.—1. An applicant's moral and ethical standing in the profession must be satisfactory to the entire board. The board must be assured that the applicant is engaged in the practice of anesthesiology as a specialty and that he intends to continue to be so engaged.

2. Membership is required in the American Medical Association or membership in such other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies shall not be required.

3. Practice must be limited to anesthesiology, in accordance with the requirements of the American Board of Surgery.

4. In exceptional instances the board may, in its discretion, accept for examination candidates who have met all the preliminary requirements and have clearly demonstrated their identity as an anesthetist over a period of years but whose formal training does not comply with the full requirements to be exacted in the future.

B. *Professional Standing*.—1. An applicant must be a graduate of a grade A school in the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or a graduate of an approved foreign school.

2. Satisfactory evidence must be supplied of completion of an internship of not less than one year in a hospital approved by the same council, or its equivalent in the opinion of the board.

3. An applicant must establish in a manner satisfactory to the Board of Anesthesiology: that he is a physician duly licensed by law to practice medicine; that he is of high ethical and professional standing, and that he has received adequate special training in anesthesiology.

C. *Special Training and Practice*.—1. Before certification the candidate must have had an active experience limited to anesthesiology of not less than four calendar years. Applicants accepted after Jan. 1, 1941, will be required to have an active experience of five years.

2. The board recommends the inclusion of at least two years of carefully supervised instruction in the clinical phases of anesthesiology in hospital clinics, dispensaries, and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the teaching and practice of anesthesiology. In addition, instruction in anatomy, physiology, pharmacology, biochemistry and other basic sciences which are necessary to the proper understanding of the problems involved in the specialty of anesthesiology is required.

(The board believes that for those entering the specialty after Jan. 1, 1942, the facilities for special training in anesthesiology will be increased and such training will be sufficiently standardized that special training in anesthesiology may be interpreted to include after that date:

(a) A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals, and laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in the special field of anesthesiology.

(b) A total period of not less than six years of special training and practice in anesthesiology after internship will be required before certification can be granted.)

EXAMINATIONS

The qualifying examination will be divided into Part I, written, Part II, oral, and Part III, practical.

PART I

1. An applicant, to be eligible for Part I, must meet all requirements and be certified by the central office of the board after his credentials have been approved by the secretary of the board, who shall have recourse to the Examination Committee in doubtful cases.

2. At the board's discretion a candidate may apply for the written examination on basic science and clinical practice on the completion of his courses of special training in these subjects.

3. Part I may be given simultaneously in several centers, throughout the United States, which the board may determine suitable for the purpose.

PART II

1. In order to be eligible for Part II, a candidate must have successfully passed Part I in addition to having met the necessary requirements and having presented definite evidence of an adequate experience in anesthesiology satisfactory to the board.

2. It is probable that Part II examinations will be held at the same time and place as the examinations of the American Board of Surgery. Later, however, as the demand grows, it may be necessary to establish subsidiary centers where this part may be held. At that time it will be necessary for the board to appoint subsidiary boards, consisting of those already qualified to actually conduct such examinations.

PART III

1. It is believed that the practical examination in this field is slightly different from that in most specialties. The examiners would be expected to observe the work of candidates in their own or similar operating room surroundings, their relations to other staff members, and investigate their professional standing.

CONDUCT OF EXAMINATION

Carefully conducted and thorough examinations will be required of candidates. The aim will be to avoid unduly exacting standards above present facilities for study and practice in anesthesiology, and on the other hand, to prevent laxity, which would nullify the main purpose of the certificate. Thus the type of the examination will depend on a careful review of the work done, years of practice, special courses of study, and professional standing of the applicant.

Written examinations will cover such topics as anatomy, biochemistry, physiology, pharmacology, pathology, physical diagnosis, therapeutics, clinical practice, and public health in relation to anesthesiology.

Oral examinations will cover topics in the above list, and such questions on physics and mechanics as are important in anesthesiology, especially dealing with electrical theories and the proper handling of high pressure gases and flammable agents.

Practical demonstrations will be required of the use of various types of apparatus and technics. Cadavers may be utilized by the candidates to demonstrate anatomical landmarks and technics important in regional anesthesia and for therapeutic and diagnostic procedures. Candidates should also be prepared to demonstrate methods of artificial respiration, and intravenous and pneumotherapy.

GRADES

A candidate must receive a passing average for each part, to be entitled to certification. No candidate shall pass a part who does not receive a grade of 60 per cent or more in each subject of such part. An average grade of 75 per cent shall be required for passing.

A candidate who fails in his examination in Part I will have his papers reviewed by the entire board and will be entitled to reexamination at yearly intervals for two consecutive years without further payment of fee. The board may, however, for sufficient reason, deny a candidate the privilege of reexamination.

FEES

The fee shall be \$75, \$25 of which must accompany application. Filing fee of \$10 included in this first payment is not returnable in case of rejection of application.

This board is a nonprofit organization, all fees to be used to extend the existing facilities for training in anesthesiology, after deducting necessary expenses for maintenance of the office, and the conducting of examinations. The board reserves the right to increase the fee when found necessary.

REVOCATION OF CERTIFICATE

All certificates issued by the board shall be subject to revocation by the board at any time, in case it shall determine in its sole judgment that a candidate who has received a certificate either was not properly qualified to receive it or has become disqualified since its receipt.

ADDITIONAL INFORMATION

Every candidate applying for certification must personally appear before the board before being certified.

Application blanks may be secured through the Secretary of the American Board of Anesthesiology. They must be completely filled out, accompanied by the other required credentials, and filed with the secretary of the board at least sixty days prior to the date of examination. Application blanks contain the following statement:

"I hereby make application to the American Board of Anesthesiology, Inc., an affiliate of the American Board of Surgery, for the issuance to me of a Certificate of Qualification as a Specialist in Anesthesiology and for examination relative thereto, all in accordance with and subject to its rules and regulations. I agree to disqualification from examination or from the issuance of a Certificate of Qualification or to forfeiture and redelivery of such certification in the event that any of the statements hereinafter made by me are false or in the event that any of the rules governing such examinations are violated by me or in the event that I did not comply with or shall violate any of the provisions of the Certificate of Incorporation or By-Laws of the American Board of Anesthesiology, Inc., an affiliate of the American Board of Surgery, or both, as then constituted. I agree to hold the American Board of Anesthesiology, Inc., an affiliate of the American Board of Surgery, its members, examiners, officers and agents free from any damage or complaint by reason of any action they, or any of them, may take in connection with this application, such examination, the grade or grades given with respect to any examination, or the failure of said board or corporation to issue to me such Certification of Qualification."

Proper forms for making application and other information will be furnished by the secretary-treasurer.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

HOWARD FOX, President, New York.

HAROLD N. COLE, Vice President, Cleveland.

C. GUY LANE, Secretary-Treasurer, 416 Marlboro Street, Boston.

CHARLES C. DENNIE, Kansas City, Mo.

J. GARDNER HOPKINS, New York.

PAUL A. O'LEARY, Rochester, Minn.

FRANCIS E. SENEAR, Chicago.

ARTHUR W. STILLIANS, Chicago.

FREDERICK D. WEIDMAN, Philadelphia.

ORGANIZATION

At the 1931 meeting of the American Dermatological Association, a committee was appointed to determine the advisability of forming an American Board for the certification of competent practitioners in this specialty similar to boards created by the ophthalmologists, the otolaryngologists and by the obstetricians and gynecologists. A similar committee was appointed by the Section on Dermatology and Syphilology of the American Medical Association at its meeting in the same year. A favorable report was rendered by each committee at the 1932 meeting of each of the above organizations.

The American Dermatological Association voted to accept the report of this committee, and the president appointed the following four members to represent the Association on the newly formed American Board of Dermatology and Syphilology:

Dr. Jay F. Schamberg, Philadelphia.

Dr. Howard Fox, New York.

Dr. Harold N. Cole, Cleveland.

Dr. Arthur W. Stillians, Chicago.

The Section on Dermatology and Syphilology of the American Medical Association also accepted the report of its committee and the chairman appointed the following members to serve as its representatives:

Dr. Howard Morrow, San Francisco.

Dr. William H. Mook, St. Louis.

Dr. George M. MacKee, New York.

Dr. C. Guy Lane, Boston.

The first meeting of the board was held in New Orleans on May 11, 1932, at which time officers were elected.

Another meeting was held on Nov. 11, 1932, in Philadelphia at which the organization was completed and resolutions were adopted concerning the proper procedure to be followed by the board. On Nov. 29, 1932, the board was incorporated under the laws of the state of Delaware.

In 1937 the American Academy of Dermatology and Syphilology was formed, and in November 1939 a plan was finally approved whereby the board would be composed of three representatives from each national dermatologic society, viz., the American Dermatological Association, the Section on Dermatology and Syphilology of the American Medical Association, and the American Academy of Dermatology and Syphilology.

PURPOSES

The board has been established primarily to determine the competence of physicians who specialize in dermatology and syphilology. It will prescribe adequate standards of fitness, conduct examinations to test the qualifications of voluntary candidates and grant certificates to candidates who successfully fulfil the requirements of the board.

A second object is to publish lists of physicians, who shall have been certified by the board, for the benefit of hospitals, medical schools, other physicians and the lay public.

A third object is to improve the standards of practice of dermatology and syphilology (1) by investigation of medical school curriculums and (2) by investigation and encouragement of adequate facilities for graduate instruction in this specialty.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in dermatology and syphilology and has successfully fulfilled the requirements of the board.

It is expected that medical schools, hospitals and physicians, as well as the lay public, will utilize the certificate from this board as a proof of adequate preparation in the field of dermatology and syphilology, and of fitness of candidates for positions under their control. For this purpose lists of those holding certificates from the board will be available for inspection and

will be published from time to time by the board. Diplomates will be identified in the Directory of the American Medical Association and the Directory of Medical Specialists.

A certificate granted by this board does not of itself confer or purport to confer, any degree, or legal qualifications, privileges, or license to practice dermatology or syphilology. The board does not intend to limit or interfere with the professional activity of any duly licensed physician. Its aim is to elevate the standard of qualification for specialists in this field and to certify as specialists those who voluntarily comply with the requirements of the board.

Certificates will be issued only to physicians in the United States and its possessions, in Canada and in Cuba.

APPLICATION AND FEE

The board desires to appraise the candidate's educational opportunities (premedical, medical and dermatologic), the character of the men under whom he has worked, his hospital and teaching positions, original investigations, contributions to dermatologic literature, membership in medical societies and his local and general reputation.

For this purpose, application must be made on a special blank, which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application should be forwarded at least two months before the date of examination together with the required reprints, photographs and the fee of \$35. This fee will not be returned, and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. Members of the board do not receive any compensation except for actual expenses connected with holding the examinations.

Make checks payable to American Board of Dermatology and Syphilology, Inc.

EXAMINATIONS

Applicants classified in group B will be required to pass a written examination. This written examination on clinical and laboratory subjects including cutaneous pathology will be held simultaneously at stated intervals in different parts of the country, approximately two months before the oral examination.

Applicants classified in both groups A and B will be required to pass an oral, clinical and laboratory examination. This examination will be conducted in a clinic or hospital ward where individual cases will be discussed with each candidate. The examination will include various basic subjects as related to the skin: histopathology, mycology, allergy and physics of physical therapy, etc.

The oral examination will be held near the time and place of the annual meeting of the American Academy of Dermatology and Syphilology. This examination will be held only at the time of regular meetings of the board.

Examinations are designed to test the candidate's fitness to practice dermatology and syphilology as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of recent literature of dermatology and syphilology and his general qualifications as a specialist in this branch of medicine.

Except in special circumstances, applicants shall take the examination within the year following the filing of application and the deposit of the fee.

Whenever an applicant fails to pass the examination, the board if requested will make suggestions as to suitable courses of instruction for the purpose of overcoming deficiencies in his knowledge of the specialty.

REEXAMINATIONS

If the candidate fails or is "conditioned" in an examination he will be admitted to a second examination after one year, but within three years, and must give sixty days' notice of his intention to appear for reexamination. If a candidate who has failed or has been conditioned does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$35 before reexamination.

A candidate having failed twice must file a new application and pay an additional fee of \$35.

REQUIREMENTS FOR CERTIFICATION

I. GENERAL REQUIREMENTS

1. High ethical and professional standing.
2. Citizenship in the United States or citizenship—meaning native citizens—in Canada and Cuba.
3. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
4. A license to practice medicine.

5. Satisfactory completion of an internship of not less than one year in a hospital approved by the same Council.

6. Adequate training in dermatology and syphilology as a specialty.

Membership in the American Medical Association is recommended.

II. SPECIAL REQUIREMENTS

Applicants for certification by the board are classed in two groups as follows:

Group A consists of physicians who have limited their practice mainly to dermatology and syphilology for ten or more years, including a period of training satisfactory to the board.

Group B consists of physicians who have practiced dermatology and syphilology at least five years, including their period of training. For group B candidates to be examined from Jan. 1, 1940, to Jan. 1, 1945, the board will require two years of full-time planned training in clinical dermatology and syphilology, including adequate instruction in the following subjects related to the skin: histopathology, mycology, physics as related to physical therapy, and allergy.

III. FUTURE SPECIAL REQUIREMENTS

Beginning Jan. 1, 1945, additional requirements will become effective. By 1940 it is expected that sufficient facilities will be developed throughout the country to provide for three years' training of graduate students in accordance with the minimum requirements suggested by the Advisory Board for Medical Specialties and outlined in a syllabus issued by the board. These minimum requirements of special training for admission to examination in 1945 shall be as follows:

1. A period of study after the internship of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council and approved by the American Board of Dermatology and Syphilology as competent to provide a satisfactory training in dermatology and syphilology.

2. This period of specialized training shall include:

(a) Graduate training in the basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in this specialty.

Instruction in the following fundamental subjects as related to the skin is deemed advisable by the board: embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and materia medica, and physics of physical therapy.

(b) An active experience of not less than eighteen months in hospitals, clinics, dispensaries or diagnostic laboratories recognized by the same Council and approved by the American Board of Dermatology and Syphilology as competent to provide an adequate preparation.

(c) Examinations in the basic medical sciences of a specialty as well as in the clinical, laboratory and public health aspects.

3. An additional period of not less than two years of study and/or practice.

Therefore, candidates beginning their training after Jan. 1, 1940, for certification by this board must plan for a three years course of systematic training.

In 1945 and thereafter admission to examination by this board will be permissible only to applicants with such training. Classes A and B will be abolished and all candidates will be required to fulfil the same requirements.

REVOCATION OF CERTIFICATES

The certificates issued by the board are issued subject to the provisions of the certificate of incorporation and of the by-laws, and each certificate is subject to revocation in the event that:

(a) the issuance of such certificate or its receipt by the physician so certified shall have been contrary to any of the provisions of the certificate of incorporation or by-laws; or

(b) the physician so certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to or could have been ascertained by the directors of the Board at the time of the issuance of such certificate; or

(c) the physician so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the Board or its representatives; or

(d) the physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the Board of Directors, moral turpitude in connection with his practice of medicine; or

(e) the physician so certified shall have had his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

INSTRUCTIONS TO APPLICANTS

Fill out application blank in detail.

Enclose fee of \$35. (Make checks payable to the American Board of Dermatology and Syphilology, Inc.)

Include photographs as directed on application blank.

Enclose reprint of each published paper, if possible.

Send completed applications and above items to the secretary.

Please indicate under No. 13 on the application blank as complete data as possible about your training in dermatology and syphilis. Indicate the month and year, if possible, or at least the number of months of the various parts of your training and also whether full time or part time. If part time indicate whether one-half day, six days a week or three days a week, etc. If dispensary service is considered as part of your training, please indicate details here as well as under No. 14.

In No. 16 indicate clearly when you limited your practice to dermatology and syphilis.

If your training and your practice overlap, please explain under No. 19.

PUBLICATIONS OF THE BOARD

1. Booklet of Information.

2. Opportunities for Graduate and Postgraduate Students in Dermatology and Syphilology, containing a list of places where instruction may be obtained, and details about these places.

3. Syllabus of graduate training.

(a) To inform the student physician, intending to specialize, of the field to be covered in his preparation and the methods by which it can be accomplished.

(b) To aid the medical schools and the dermatological departments of medical schools and hospitals by outlining the scope of teaching required for specialization in dermatology and syphilology.

Further information may be obtained from the secretary-treasurer.

AMERICAN BOARD OF INTERNAL MEDICINE, Inc.

ERNEST E. IRONS, Chairman, Chicago.

REGINALD FITZ, Vice Chairman, Boston.

WILLIAM S. MIDDLETON, Secretary-Treasurer, 1301 University Avenue, Madison, Wis.

DAVID P. BARR, St. Louis.

LOUIS HANMAN, Baltimore.

WILLIAM J. KERR, San Francisco.

JONATHAN F. MEAKINS, Montreal, Quebec.

JOHN H. MUSSEY, New Orleans.

G. GILL RICHARDS, Salt Lake City.

"... the membership of the board shall be maintained at the ratio of five members from the American College of Physicians and four members from the Section on the Practice of Medicine of the American Medical Association and that at least three of the members of the board from the American College of Physicians and two members of the board from the Section on the Practice of Medicine of the American Medical Association shall be of professorial rank in approved medical schools of the United States or Canada."

"Sec. 5, Art. 5, Articles of Incorporation."

"The term of office of members of the board succeeding the original board members shall be three years and until their successors are elected and qualified, and no such member shall serve more than two consecutive three year terms."

"Sec. 7, Art. 5, Articles of Incorporation."

PURPOSE AND OBJECTIVE

The purpose and objective of the board is the certification of specialists in the field of internal medicine, and the establishment of qualifications for such certification and of the procedure necessary for the accomplishment of such objective.

While the board is at present concerned chiefly with the qualification and procedure for certification in the general field of internal medicine, it is intended to inaugurate, as soon as practicable similar qualification and procedure for additional certification in certain of the more restricted and specialized branches of internal medicine, as gastro-enterology, cardiology, metabolic diseases, tuberculosis, allergic diseases, et cetera. Such special certification will be considered only for candidates who have passed the written examination required for certification in general internal medicine. The operation of such a plan will require the active cooperation and participation of recognized representatives from each of such special fields of medicine.

VALUE OF CERTIFICATION

1. An attest of special training and qualification for the practice of internal medicine as a specialty.

2. Publication with internists proper designation in a special registry of certified specialists and in the American Medical Directory.

QUALIFICATIONS OF CANDIDATES

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

1. GENERAL.

A. Satisfactory moral and ethical standing in the profession.

B. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical society or societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies shall not be required.

2. PROFESSIONAL.

A. Graduation from a medical school of the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association.

B. Completion of an internship of not less than one year in a hospital approved by the same council.

C. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the aforementioned council, the Advisory Board for Medical Specialties, and the National Board of Medical Examiners.

3. SPECIAL TRAINING.

A minimum of five years must elapse after completion of a year of internship in a hospital approved for intern training before the candidate is eligible for admission to an examination.

A. Three years of this period must be devoted to special training in internal medicine. This requirement should indicate a period of at least several months of graduate work under proper supervision in anatomy, physiology, biochemistry, pathology, bacteriology or pharmacology, particularly as related to the practice of internal medicine. This work may be carried on in any domestic or foreign medical school or laboratory recognized by the Council on Medical Education and Hospitals of the American Medical Association as offering appropriate facilities for this type of postgraduate training; or it may include a period of at least several months of graduate work under proper supervision in internal medicine or in its restricted and specialized branches in any domestic or foreign hospital, clinic or dispensary, or under the immediate preceptorship of an internist recognized by the above council as offering appropriate facilities for this type of postgraduate experience.

B. A period of not less than two years of special practice in the field of internal medicine or in its more restricted and specialized branches.

MEMORANDUM FOR THE GUIDANCE OF CANDIDATES

The American Board of Internal Medicine does not propose to establish fixed rules for the preliminary training of candidates for certification in this field. Broad general principles for training, however, may be outlined, although such suggestions as are made must of necessity be subject to constant changes reflecting the dynamic nature of the specialty.

1. A sound knowledge of physiology, biochemistry, pharmacology, anatomy, bacteriology and pathology in so far as they apply to disease is essential for continued progress of the individual who practices internal medicine. Such knowledge may be obtained in a number of ways:

A. By properly arranged and supervised graduate courses;

B. By the opportunities for study afforded by the appointment to a junior position in a department of physiology, biochemistry, pathology, etc. (see above) with attendance upon advanced lectures in the other subjects;

C. By advanced study in these subjects while an intern or resident medical officer, and by the application of the principles involved to patients under one's control;

D. By the detailed study, under supervision, of a problem or topic in medicine in which the student brings the basic facts of physiology, pathology, etc., into direct relation with the concrete clinical problem. The analysis of a problem with detailed knowledge of its fundamental pathologic or physiologic background does much to stimulate thoroughness, clear thinking and progress.

2. A portion of the written examination is designed to test the candidate's knowledge in these "preclinical" subjects and especially in their application to disease rather than their purely laboratory aspects.

3. The mere factual knowledge of medicine and its basic sciences is not sufficient. The candidate must have had training in their use in furthering his understanding in clinical medicine. This implies practical experience under the guidance of older men who bring to their clinical problems ripe knowl-

edge and critical judgment. Preparation to meet this requirement adequately may be even more difficult to obtain than the so-called scientific training. It may, however, be acquired in the following ways:

A. By work in a well organized hospital outdoor clinic conducted by competent physicians;

B. By a prolonged period of resident hospital appointments likewise directed by skilled physicians;

C. By a period of training in intimate association with a well trained and critical physician who takes the trouble to teach and guide his assistant rather than to expect him only to carry out the minor drudgery of a busy practice.

4. The board does not consider it to the best interests of internal medicine in this country that rigid rules be formulated as to where or how the training outlined above is to be obtained. Medical teaching and knowledge are international. The opportunities of all prospective candidates are not the same. Some may have the opportunity of widening their knowledge by a period of study abroad. Others, at the other extreme, may be restricted to a comparatively narrow geographic area and their more detailed training must be obtained in short periods of good study scattered over a longer time. Although it is required that at least five years must elapse between the termination of the first intern year and the date when the candidate is eligible to take the examination, a longer period is advisable. The board wishes to emphasize that time and training are but a means to the end of acquiring a broadness and depth of knowledge of internal medicine which the candidate must demonstrate to the board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge as best he may rests with the candidate, while the responsibility of maintaining the standard of knowledge required for certification devolves on the board.

METHOD OF EXAMINATION

The examination required of candidates for certification as specialists in internal medicine will comprise Part I (written) and Part II (practical or clinical).

Part I. The written examination is to be held simultaneously in different sections of the United States and Canada on the third Monday of February and October of each year. This examination will be divided into a morning and an afternoon session of three hours each, and the two sessions A and B will include the following:

A. Question in applied physiology, anatomy, physiological chemistry, pathology, bacteriology and pharmacology as related to internal medicine as well as the cultural aspects of medicine.

B. Questions in general internal medicine.

Part II. Candidates successful in the written tests will be eligible for the practical or clinical examination, which will be conducted by the members of the board near the time and place of the annual meeting of the American College of Physicians and of the American Medical Association. This examination is conducted at the bedside, and each candidate will be assigned one or more patients in the hospital. A written record of the clinical history and examination is required which forms the basis of the oral conference conducted by one or more examiners.

APPLICATION

Candidates for examination shall make their application on a prescribed form which may be obtained from the office of the secretary-treasurer.

The application shall contain a record of the candidate's premedical and medical training as well as of internships, graduate study, hospital or dispensary staff appointments, teaching positions, membership in medical societies, medical papers published and the names of two well known internists to whom the board may refer for professional and character reference.

The application shall also be accompanied by two recent, unmounted, signed photographs of the candidate and the registration and examination fee of \$40, which fee will cover both the written and practical examinations. The registration fee of \$10 is not refundable. An additional fee of \$10 will be required when the certificate is issued.

CERTIFICATES

The certificate issued by the American Board of Internal Medicine shall be in such form as to comply with the articles of incorporation and the by-laws and shall be signed by the officers and members of the board, and shall bear the official seal of the board.

Certificates of the board will be issued to candidates who have satisfactorily completed the written and practical examinations, and been found qualified by the board to practice the specialty of internal medicine.

REVOCATION OF CERTIFICATES

The American Board of Internal Medicine shall have the sole power, jurisdiction and right to determine and decide whether or not the evidence or information placed before it is sufficient to constitute grounds for revocation of any certificate issued by this board, and the decision of the board in the premises shall be final.

All official correspondence should be addressed to the secretary-treasurer.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, Inc.

WALTER T. DANNREUTHER, President, New York.
JOSEPH L. BAER, Vice President, Chicago.

LOUIS E. PHANEUF, Vice President, Boston.

PAUL TITUS, Secretary-Treasurer, 121 South Highland Avenue, Pittsburgh.

E. A. SCHUMANN, Member of Executive Committee, Philadelphia.

JENNINGS C. LITZENBERG, Minneapolis.

G. D. ROYSTON, St. Louis.

R. D. MUSSEY, Rochester, Minn.

L. A. EMGE, San Francisco.

ORGANIZATION

In 1930 the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons, the American Gynecological Society, and the Section on Obstetrics, Gynecology, and Abdominal Surgery of the American Medical Association, each elected three Fellows to constitute the American Board of Obstetrics and Gynecology.

Dr. Walter T. Dannreuther of New York, Dr. Paul Titus of Pittsburgh and Dr. Grandison D. Royston of St. Louis were appointed to represent the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons; Dr. Jennings C. Litzenberg of Minneapolis, Dr. Joseph L. Baer of Chicago, and Dr. E. A. Schumann of Philadelphia were appointed to represent the American Gynecological Society; Dr. Fred L. Adair of Chicago, Dr. R. D. Mussey of Rochester, Minn., and Dr. E. D. Plass of Iowa City, Iowa, were appointed to represent the Section on Obstetrics and Gynecology of the American Medical Association. Dr. Adair and Dr. Plass were succeeded following their recent resignations by Dr. L. E. Phaneuf of Boston and Dr. L. A. Emge of San Francisco.

The board was incorporated and organized and held its first meeting in September 1930. At that time the By-Laws were adopted and provision was made by resolutions for its proper functioning.

This board had been in the process of organization since 1927 and put into action a determined effort on the part of these three national organizations to improve the standards of practice of obstetrics and gynecology.

Experienced practitioners of the specialty are required to undergo a practical clinical examination, whereas a younger group has both a written and clinical examination and must also submit records of a group of cases in order to qualify for certification.

After 1941, no such distinction will be made, and all applicants will be obliged to fulfill all of the requirements, including the written examination in obstetrics and gynecology and to submit case records, as well as the general oral-clinical and pathological examination in obstetrics and gynecology.

PURPOSES

First. To elevate the standards and advance the cause of obstetrics and gynecology.

Second. To determine the competence of specialists in obstetrics and gynecology.

Third. To grant and issue certificates, or other evidence of special knowledge in the field of obstetrics and gynecology, to voluntary applicants and candidates therefor.

Fourth. To arrange, control, and conduct examinations to test the qualifications of voluntary candidates.

Fifth. To serve the public, hospitals and the medical schools by preparing lists of practitioners who shall have been certified of incorporation in which it is stated that "the nature of the business and the objects or purposes proposed to be transacted, promoted and carried on by it" are as follows:

"To encourage the study, improve the practice, and advance the cause of obstetrics and gynecology, subjects which should be inseparably interwoven; and to grant and to issue to physicians duly licensed by law, certificates or other equivalent recognition of special knowledge in obstetrics and gynecology."

NO DEGREES OR LEGAL RESTRICTIONS

Each certificate granted or issued does not of itself confer or purport to confer upon any person any degree or legal qualifications, privileges or license to practice obstetrics or gynecology, nor does the board intend in any way to interfere with or limit the professional activities of any duly licensed physician. Its chief aim is to standardize qualification for specialists in obstetrics and gynecology, and to certify as specialists those who voluntarily comply with the board's requirements.

VALUE OF CERTIFICATE

The national obstetrical and gynecological organizations, which have participated in the formation of the board and are sponsoring its activities, as well as other societies, attach considerable importance to its certificate. Both the medical and the lay public, including hospital directors, have come to utilize the certificate from this board as a means of determining who are well grounded as specialists in obstetrics and gynecology.

Lists of those holding certificates from this board who are limiting their practice to obstetrics and gynecology are published and issued from time to time by the board; similar lists are published by the *American Journal of Obstetrics and Gynecology*, and also appear in the *American Medical Directory*. This latter indicates diplomates of this and other boards by means of numerical symbols appearing in the biographic records. This directory, however, does not give such special recognition to diplomates who fail to maintain membership in the American Medical Association, or the Canadian or other medical societies recognized for this purpose.

A joint directory of specialists certified by the thirteen major and two affiliate special boards was published in 1940.

This board holds active membership in the Advisory Board for Medical Specialties.

This board, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association, is conducting a survey of institutions providing acceptable residencies and internships in obstetrics and gynecology.

Applicants sign an agreement empowering the board to revoke their certificates and to remove their names from its lists, if they fail to abide by the regulations governing limitation of practice to the specialty or otherwise violate the standards of ethical practice.

For emphasis it is repeated that the board does not intend to, and cannot, in any way interfere with or limit the professional activities of any duly licensed physician, but its aim is toward adequate qualifications for those who claim to be specialists in obstetrics and gynecology.

ELIGIBILITY REQUIREMENTS

Requirements for Applicants. Each applicant, before he shall become eligible to receive such certificate or other evidence of recognition, (a) must establish in a manner satisfactory to the board of directors that he is a physician duly licensed by law to practice medicine, that he is of high ethical and professional standing, and that he has received adequate training in obstetrics and gynecology as a specialty; (b) must have had conferred upon him a degree in medicine by an institution of learning approved by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association; (c) must make application to the examiners whose duty it shall be to investigate the applicant's credentials and make a survey of his character; (d) must assure the board that he is limiting his practice to obstetrics and/or gynecology and that he intends to continue to do so, and (e) should have membership in the American Medical Association, or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

Each candidate should have certain fundamental knowledge of the basic essentials of anatomy, pathology, bacteriology, physiology, pharmacology, and therapeutics as related to the practice of obstetrics and gynecology. Clinical training should consist, subsequent to graduation, of at least one year's general rotating internship, and thereafter a special residency in obstetrics and gynecology for a period of at least three years, not necessarily consecutive. The board accepts the fifth or "intern" medical school year required at some schools in lieu of the usual fifth or intern "clinical training" year following graduation. As a substitute for special training, service with a qualified preceptor, preferably one who has been certified by the board, may be acceptable. The exact time basis for this has not been specified, and each case will be reviewed and decided separately by the credentials committee. The time for this type of training will vary with the amount of work done

with the preceptor. At least a fundamental knowledge of both obstetrics and gynecology is essential regardless of whether a candidate's practice is limited to one or the other branch. As heretofore, all candidates will be required to stand examination in both branches of the specialty, regardless of the fact that the major part of their practice may be in one or the other branch of the specialty.

This board deprecates the practice of obstetricians and gynecologists engaging in other fields of practice than that in which they profess to be specialists. The board does not exclude from examination, however, obstetricians or gynecologists who practice abdominal surgery and urology in the female, as well as breast surgery, because of the correlation of these activities. The board has ruled that physicians who accept male patients in their private or other practice, for operative or other care, cannot be regarded as specialists in obstetrics and gynecology. Special certifying boards in general surgery and internal medicine have now been organized and such individuals should apply to these boards for certification.

Application must be on a special blank which may be procured from the secretary and forwarded with the other required credentials and the application fee. Applications must be in the office of the secretary at least ninety days prior to the date of examination.

CLASSIFICATION OF APPLICANTS

Until Jan. 1, 1942, applicants for such certificates or other recognition shall be classified by the credentials committee as follows:

Group A. Those who have limited their practice to obstetrics and/or gynecology for a period of ten years or more, having had adequate special training following a one year general internship.

Applicants who have qualified under group A shall be required to undergo and pass a practical, oral, clinical and laboratory examination, including obstetrical and gynecological pathology. The board of directors may grant and issue a certificate or other evidence of recognition to each such applicant who shall have passed such examination in a manner and with a grade satisfactory to the board of directors, and who shall have met all other requirements therefor as hereinabove provided. (After 1941 case records and written examinations will also be required as at present for group B.) As heretofore, all candidates will be required to stand examination in both branches of the specialty, regardless of the fact that the major part of their practice may be in one or the other branch of the specialty.

Group B. Those who have had: (1) at least one year of intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, (2) five years or more practice thereafter, including at least three years of special training in obstetrics and/or gynecology satisfactory to the board of directors, and (3) who are now limiting their practice to obstetrics and/or gynecology. Opportunity for personal responsibility during this period of training is highly desirable.

Applicants who have qualified under group B shall be required to take and pass a written clinical and laboratory examination in obstetrics and gynecology, including obstetrical and gynecological pathology, as well as an oral, practical examination. Each candidate shall submit 50 typewritten case reports of major pathological obstetrical and/or gynecological cases with or without operative procedures. After Jan. 1, 1942, case records must be of patients treated within four (4) years of the date of the candidate's application. The number of residency cases submitted should not be more than half (25) of the total number of fifty (50) cases required. Candidates must attain a passing grade in both the written examination and case histories before becoming eligible for the oral, clinical, and pathological part of the examination. The board of directors may grant and issue a certificate to each such candidate who shall have passed such examination and who shall have submitted reports on such cases in a manner and with a grade satisfactory to the board of directors, and who shall have met all other requirements as hereinabove specified.

Effective Jan. 1, 1942, the requirements for all candidates will be changed to be as follows: Those who have had: (1) at least one year of intern service in a hospital approved by the Council on Medical Education and Hospitals of the A. M. A., (2) a minimum of seven years of practice thereafter, including at least three years of special training in obstetrics and/or gynecology satisfactory to the board of directors, and (3) who are now limiting their practice to obstetrics and/or gynecology. Opportunity for personal responsibility during their period of training is highly desirable.

APPLICATION BLANK AND FEES

Application must be made on a special blank which may be procured from the secretary and forwarded with the other required credentials and the application fee. The secretary cannot make any eligibility rulings. These are made only by the credentials committee after reviewing the candidate's formal application, which must be completely filled out and previously filed with the secretary. Applications cannot be considered for classification and action by the credentials committee unless accompanied by an application fee of \$15, which is not returnable.

The examination fee for candidates is \$85, payable when the candidate is notified of his acceptance for examination. This examination fee shall not be returnable after the candidate has been officially accepted by the credentials committee and notified to report for examination. If a candidate fails in his examination he will be admitted to a second examination after one year but within three years without additional fees. After two failures an applicant must file a new application and pay fees, as above, before the third examination.

Applicants declared ineligible for admission to examination may reopen their applications within one year of its filing date without payment of an additional application fee.

Applications and application fees must be in the office of the secretary at least ninety days prior to the scheduled date of the examinations.

The fees, totaling \$100, have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expenses.

Applicants who fail to exercise the examination privilege within three years of the date of filing the application are required to file a new application and pay a new application fee.

EXAMINATIONS

Written examinations are held simultaneously once yearly in various cities of this country and Canada. Arrangements will be made for candidates to report in any convenient city where there may be a diplomate of this board to conduct or supervise the written examination sent out under sealed cover from the board's office. Case histories must be submitted to the local examiner at the same time.

The written examination and submission of case histories is scheduled for the first Saturday of January. Application on an official application form for admission to this examination must be filed in the office of the secretary at least ninety days prior to this date. Grades cannot be mailed from the secretary's office until about March 15.

Part I of the examination must be taken by all applicants classified in group B, but not by those in group A until 1942.

Part I consists of a comprehensive written examination and the filing of fifty case histories. Only one group B, Part I, examination will be held yearly. No group B candidate is eligible for the oral and pathological examinations until he has passed the written portion and his case histories have been found satisfactory. The passing grade for the written examination and case records is 75 per cent, and a candidate whose grade in either or both falls below 75 per cent is conditioned. Either or both of these conditions must be removed before the candidate is eligible for Part II. Reexamination for the removal of conditions in Part I may be taken at any regular examination after one year but within three years without payment of an additional fee. Candidates who successfully complete the Part I examinations proceed automatically to the Part II examinations held later in the year.

The written examination consists of questions on both obstetrics and gynecology, as evidence of a fundamental knowledge of both branches is required of all candidates. The fifty case records of each group B candidate must be presented with his examination paper to the local examiner. Both the written examination papers and typewritten case records will be reviewed by an examiner located in a remote district from that of the candidate.

Part II. The general oral-clinical and pathological examinations given all candidates will be conducted by the entire board at or near the time and place of the annual meeting of one or more of the national societies represented on this board, usually that of the American Medical Association. Applications must be filed at least ninety days prior to the date of examination. This examination is given to all applicants in group A and group B. The candidates will be expected to identify and discuss several obstetrical and gynecological pathologic specimens and histologic sections. As heretofore, all candidates will be required to stand examination in both branches of the specialty, regardless of the fact that the major part of their

practice may be in one or the other branch of the specialty. An endeavor will be made to adapt the details of the oral examination to each candidate's experience and practice, and will be particularly directed to ascertain his familiarity with recent obstetrical and gynecological literature, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology.

Examiners report orally upon each candidate to the assembled board, after which the results of their examinations are considered jointly. After a general consideration of the details of the candidate's oral and pathological examination, including a review of his capability and general adaptability, the candidate is passed or failed by the entire board. No conditions are given in Part II of the examination. When a candidate fails in Part II of the examination, he is not required to repeat Part I, but to take a reexamination in the oral, clinical, and pathological portions only. Reexamination may be taken within three years of the original examination or first failure.

After 1941, the distinction between candidates in group A and group B will be abolished. After that time new rulings similar to those now pertaining to group B will apply to all applicants, and every candidate will be required to undergo the written examinations and present case records (Part I), as well as the oral-clinical and pathological examinations (Part II) in both obstetrics and gynecology.

CASE RECORDS

(After January 1, 1942, case records submitted must be of applicants treated within four (4) years of the date of the candidate's application. The number of residency cases submitted should not be more than half (25) of the total number of fifty (50) cases required.)

Case histories need not be copied verbatim from the hospital records but must be sufficiently complete so that the examiner can determine the diagnosis of existing conditions and evaluate the judgment of the candidate in his choice of procedure. Each history must give the hospital number and name of the hospital at which the patient was treated or operated upon, together with all pertinent dates. Histories must be typewritten on standard size paper, 8½ x 11 inches, assembled by individual cases, and submitted without any form of binding other than light weight paper folders. The following data should be as complete as possible: essential points in history and examination; the clinical diagnosis and in operative cases preoperative diagnosis, ample summary of operative procedure; clinical and pathological diagnosis; summary of postoperative course with special reference to morbidity; findings at time of discharge from hospital and at six months "follow-up."

In both obstetrical and gynecological case histories not more than ten major selected nonoperative cases may be included. When pathological tissue is removed, adequate gross and microscopic descriptions are required. The candidate and the pathologist are required to employ the accepted nomenclature in the classification of gross and microscopic reports of pathological findings.

The obstetrical case records should show the date of the first prenatal visit and any special features bearing on the case. The examination of obstetric patients should include a routine serologic test for syphilis; also blood grouping or typing should be noted on histories of patients requiring transfusions. The weight and condition of the child at birth and at the time of discharge from the hospital should be shown on the obstetric history.

A final statement must be prepared for each case, to include an account of the candidate's personal observations of the case both prior to and subsequent to operation. These data must include (1) the basis for the diagnosis, (2) the facts that determined the course of the treatment, and (3) critical conclusions to be drawn from the outcome of the case. Case reports which do not include such discussion and comments will not be reviewed by the examiners. Obstetrical histories which omit measurements of the pelvic inlet and outlet will be considered incomplete.

The group of histories must include a variety of material rather than a number of cases of one type. The histories should be sufficiently detailed so that the examining board, after a careful reading of the records will be able to answer the following questions:

1. Is the diagnosis warranted by the recorded data?
2. If not, how lacking?
3. Are the indications for operation clearly stated?
4. Is the technic satisfactorily described?
5. Do the results justify the procedure?
6. Do the conclusions drawn indicate a grasp of the subject?

Only those records which carry the candidate's personal deductions, conclusions, and comments will be credited toward

the fifty, and these records must be diversified. Case records which do not conform to board regulations will not be graded.

Note: Two complete index lists of these cases must accompany the records. Separate lists should be made for each individual hospital at which operations were performed. These lists must state the candidate's name, and at the head of each page the name and address of the hospital, the name of the patient, admission number, date of admission, date of operation, and date of discharge. The candidate must have these lists verified by the librarian, or preferably the superintendent, of each individual hospital from which these case records come. All verifications must be formally signed by the responsible hospital official.

Case histories are to be presented with the complete examination paper to the examiner conducting the written examination. They are not to be sent by the candidate to the secretary.

The final action of the board is based upon the candidate's professional record, training and attainments, as well as on the results of his formal examination.

Communications should be addressed to the secretary-treasurer.

ORIGIN, AIMS AND METHODS

In 1913 the American Ophthalmological Society, the Section on Ophthalmology of the American Medical Association, and the American Academy of Ophthalmology and Otolaryngology appointed committees to report on ophthalmic education.

In 1914 these committees recommended that medical schools of the first class establish graduate courses in ophthalmology leading to an appropriate degree, and that these courses should represent not less than two years of systematic work subsequent to taking the degree of Doctor of Medicine. There was unanimous agreement as to the need of systematized and standardized training of those who are to practice ophthalmology, but it was clear that, in the near future, the number who would take the complete course leading to such a degree would be small. Moreover, such a course would not solve the problem of differentiating, in some degree, between the competent and the incompetent among those now in practice in ophthalmology. The committees were continued and, in 1915, they made further recommendations, as a result of which a joint board was created consisting of three representatives from each of the three special societies.

In 1916, after much preliminary work, this board was organized as the American Board for Ophthalmic Examinations (later changed to "American Board of Ophthalmology"). It was incorporated May 3, 1917.

In 1934 the plan of organization was changed so that each component society elects four members, instead of three, to form the board. The members of this board are chosen in the same manner as the presiding officers of these societies are chosen. One is elected each year by each of the societies represented on the board, to serve for four years.

As other specialties formed boards similar to the American Board of Ophthalmology the need for some supervising and coordinating control led to action by the American Medical Association in 1933 authorizing the Council on Medical Education and Hospitals: (1) to formulate standards of administration, based on those of the American Board of Ophthalmology, of Otolaryngology, of Gynecology and Obstetrics, and of Dermatology and Syphilology; and (2) to recognize officially new boards meeting these standards.

The Constitution of the Advisory Board for Medical Specialties which was organized in 1934 states that: "This board shall act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists."

CHIEF FUNCTIONS

1. To establish standards of fitness to practice ophthalmology cooperating with hospitals and graduate schools of medicine.
2. To arrange and conduct examinations to test the qualifications of those who practice ophthalmology, and to confer certificates upon those who meet the standards established by the Board.
3. To act as preceptors for prospective students of ophthalmology.

NO DEGREES

The conferring of a degree is left to the universities, where it belongs, and the board makes no attempt to control the practice of ophthalmology by any license or legal regulation whatever. It simply aims to establish a standard of fitness to practice ophthalmology, and to certify any who, voluntarily, apply and satisfy the board of their qualifications.

The following is the wording of the present certificate:

The American Board of Ophthalmology hereby certifies that(name)..... has pursued an accepted course of graduate study and clinical work, and has successfully passed the examination in ophthalmology conducted under the authority of this Board.

Date.....

Signatures of members of the Board

Many special eye hospitals as well as general hospitals in all parts of the country require the certificate for appointment or promotion on their staffs. In addition, many societies now require the certificate as a prerequisite for membership.

The number of institutions and societies which require the certificate of the board is increasing.

The American College of Surgeons recognizes the certificate of this board as evidence of academic fitness in ophthalmology. It requires from candidates for its Fellowship who hold such certificates only half as many case histories as from those who are not so certificated.

Up to Jan. 1, 1940, approximately 1,700 ophthalmologists have received the certificate of the board.

FEEES

The fee for the examination and the certificate of the American Board of Ophthalmology is \$50. Of this sum \$25, which is not returnable, must accompany the application. The balance of \$25 must be paid when the certificate is ready for issuance.

If a candidate fails in the written examination, he may be admitted to a second examination within three years, for which there will be an additional fee of \$10.

Applications expire three years from date of application. If a candidate has not appeared for examination before expiration of his application, he will be required to apply again and pay an additional application fee of \$25.

The fees of candidates are used solely for defraying the actual expenses of the board. The members of the board and their associates receive no emoluments.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

1. Application on special blank, which may be obtained from the secretary, must be filled out accurately. Letters of endorsement from two well known physicians (preferably ophthalmologists) together with any other required credentials must accompany the application and must be sent to the secretary at least ninety days before the candidate expects to appear before the board.

2. The candidate must have high ethical and professional standing in his community.

3. Membership in the American Medical Association or such other societies as are recognized for the purpose by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the Board; if he has been in practice less than ten years he should obtain the certificate of the National Board of Medical Examiners.

4. A list of papers or books published by the candidate must be submitted.

5. Reports of ten cases of varied character which have been observed and treated by the applicant are required.

6. An examination divided into Part I (written) and Part II (clinical, practical and laboratory). In both of these examinations a knowledge of the practical application of the basic sciences of ophthalmology will be required.

7. Citizenship in country where candidate practices.

The final action of the board is based on the candidate's professional record, training and attainments as well as on the results of his formal examinations.

GENERAL EDUCATIONAL REQUIREMENTS

(Applicable as far as possible after 1942)

1. A degree from a medical school of high standing satisfactory to the board and approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the board. He may be required to obtain the certificate of the National Board of Medical Examiners.

2. Completion of an internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

(Applicable as far as possible after 1942)

A period of combined study, training and practice of not less than three years in approved medical schools, hospitals, clinics, dispensaries, laboratories, perceptorships and private practice.

(A total of five years will be required of candidates practicing eye, ear, nose and throat.)

1. This shall include graduate study of the basic medical sciences which are fundamental to the intelligent practice of ophthalmology, particularly: anatomy, histology, embryology, optics, physiologic optics, visual physiology and psychology, pathology, bacteriology, pharmacology. Mere factual knowledge of these subjects is not sufficient. The candidate must have had training in their application and in their use in clinical ophthalmology, especially in refraction, disorders of motility and binocular vision, perimetry, and in the skilful adjustment and use of instruments such as the ophthalmoscope, retinoscope, slit lamp and microscope.

2. Active clinical experience in approved hospitals, clinics, dispensaries and private practice. Library and laboratory facilities should be utilized for the intensive study of cases.

The subject matter to be covered under 1 and 2 is outlined in the syllabus prepared by the board.

These requirements may be met in various ways:

BASIC STUDIES

A—By courses in approved graduate medical schools.

B—By the opportunities for study afforded by the appointment to a junior position in one of the departments with attendance at advanced lectures in the other subjects.

C—By advanced study of these subjects while a resident and by application of the principles involved to patients under one's control.

D—By the detailed study, under supervision or as assistant to an experienced research worker, of some problem or topic which brings the basic facts of physiology, pathology, etc., into direct relation with the concrete clinical problem. The analysis of a problem with detailed knowledge of its fundamental physiologic and pathologic background does much to stimulate thoroughness, clear thinking and progress.

CLINICAL EXPERIENCE

A—By residency in an approved hospital. The most desirable of these residencies have regular lectures covering the whole field of clinical ophthalmology and of the basic subjects as applied in clinical practice. Many of these have seminars at which residents report cases which they have carefully worked up. These are discussed by the other residents and by the staff and the method of presentation as well as the subject matter critically considered.

B—There are many residencies, usually of 12 months, which do not furnish regular instruction by lectures and quizzes and seminars. If he has access to a good library and laboratory, the student can learn a great deal and has some advantages over the man who expects to be "spoon-fed." The syllabus prepared by the board will guide him in his selection of topics to be studied.

C—There are some opportunities to continue the study and experience by securing appointments as fellows.

D—By a period of training in association with a well trained and critical ophthalmologist who takes the trouble to teach and guide his assistant.

E—After completing a residency it is of great advantage to secure a position in a clinic as fellow or assistant. This may require only part time work, but due credit will be given. Its value to the student depends on how much study he puts into it and on how competent his seniors are.

F—Research under competent critical and sympathetic supervision will give first hand insight into (1) the methods whereby old knowledge was and new knowledge is acquired, and (2) the pitfalls which accompany attempts to enlarge the sphere of knowledge. Only in this way can the candidate evaluate facts

of the past and present in the intelligent critical way which is expected of the specialist.

The candidate who cannot secure the type of residency he desires should not despair, for his progress depends far more on how he uses his opportunities than on the opportunities themselves.

WHAT CONSTITUTES THE EXAMINATION

In determining the question of certification, the examiners rely on the following criteria:

1. The applicant's professional record;
2. The applicant's case reports;
3. A written examination;
4. A practical clinical and laboratory examination.

CASE REPORTS

Detailed instructions for the preparation of case reports should be obtained from the secretary.

WRITTEN EXAMINATION: PART I

The written examination may be given simultaneously in as many cities as the board may determine suitable for the purpose. A candidate, to be eligible for Part I, must meet all general requirements. Arrangements will be made for candidates to report in a convenient city where there may be a board member, or an associate member, to conduct and supervise the written examination.

These examinations will not be given at the time of the oral and clinical examination or board sessions but will be held at least sixty days before such examinations simultaneously in different parts of the country at places reasonably convenient to candidates.

No candidates shall be eligible for the practical examination until he has passed the written examination and his case reports have been found satisfactory. In the event of failure in either or both of these preliminary tests, a candidate is conditioned and the conditions must be removed before the candidate is eligible to appear for the practical (Part II) examination.

The written examination questions will be on all subjects as follows:

External Diseases.	Perimetry and Campimetry
Ophthalmoscopy	Relation of the Eye to General Diseases
Pathology-Histopathology	Therapeutics and Operations (including Practical Surgery)
Refraction and Retinoscopy	Optics and Visual Physiology
Anatomy and Embryology	
Ocular Motility	

Written examination papers will be reviewed by examiners who reside in districts remote from those in which the candidate practices.

PRACTICAL AND CLINICAL EXAMINATION: PART II

The purpose of the examination is to determine the competence of the candidate to practice ophthalmology.

Candidates must be prepared to be examined in the whole field covered by the syllabus of the board. The time spent in preparation will count less than the knowledge and experience acquired as shown on examination.

The subdivisions of the practical examination are as follows:

1. External diseases of the eye, lacrimal passages, etc., including inspection, focal illumination, use of loupe and slit lamp, examination of reactions of the pupil, of tension by tonometer and by fingers.

2. Ophthalmoscopy. Several patients will be examined by the candidate and the findings described or drawn. The ability to see with the ophthalmoscope and to interpret what is seen, and the systematic and thorough methods of examination used by the candidate will count for more than mere statement of diagnosis. A candidate should bring his own ophthalmoscope so that he may not suffer the handicap of an unfamiliar instrument.

3. Pathology. The candidate should be familiar with general clinical pathology as well as the etiology, pathology, and bacteriology of diseases of the eye. He will be asked to examine microscopic slides and to recognize ordinary normal and pathologic histology of the eye and to identify the commoner microorganisms.

4. Refraction. A candidate will examine patients and show mastery of various methods, and of the principles of refraction and of retinoscopy. He should bring his own retinoscope.

5. Ocular Motility. The candidate will demonstrate upon patients his familiarity with routine methods of examination for abnormalities of the ocular muscles.

6. Practical Surgery. A candidate will demonstrate his surgical technique upon animals' eyes. To have the advantage of using instruments with which he is familiar, he should bring his own equipment for performing a regular combined extraction of the lens.

DATES OF PART II EXAMINATION

Examinations will be held annually at or near the time and place of the meeting of the American Medical Association; also at other times and places at the discretion of the board, depending on the number of applications from any region.

Notices of all examinations will be found in *The Journal of the American Medical Association*, and in the special journals of ophthalmology.

REEXAMINATION

Candidates may be reexamined as often as they desire, provided they give satisfactory evidence of adequate preparation. Six months must elapse between examinations and the board may, at its discretion, deny the candidate the privilege of reexamination.

REVOCATION OF CERTIFICATE

Any certificate issued by the board shall be subject to revocation by the board at any time in case it shall determine in its sole judgment that a candidate, who has received the certificate of the American Board of Ophthalmology, either was not properly qualified to receive it, or has since its receipt become disqualified.

PREPARATORY GROUP

In establishing a preparatory group of prospective candidates for its certificate, the American Board of Ophthalmology plans to assist physicians who wish to study ophthalmology so that they will be acceptable as candidates for examination and certification when they have completed the requirements.

Any graduate or undergraduate of an approved medical school is eligible to make application for membership in this group. Candidates so applying will be notified officially by the secretary when the board has accepted their applications. If accepted, data will be sent concerning ethical and educational requirements. Syllabuses and other information will be made available to them. The board desires to help candidates improve their opportunities so that they will be fully prepared for the examination.

It is essential that candidates conduct themselves in an entirely ethical manner to the end that they bring honor to the profession.

Information and counsel will be available at all times to accepted candidates in this group through advisers who are members or past members of the board.

Members of the preparatory group must keep a summarized record of their activities, two copies of which will be sent to the secretary in January of each year and will be incorporated in the final application for examination and certification.

The fee for application for membership in the preparatory group is \$10. This will be deducted from the \$50 which is required of every candidate for examination. When the candidate makes application for the examination, he will be required to pay \$25, and the balance of \$15 must be paid when the certificate is issued. No fees will be refunded.

It is of increasing importance that a physician specializing in diseases of the eye obtain the certificate of the American Board of Ophthalmology. The American Medical Association will especially designate certificated ophthalmologists in future directories. A special directory of all certificated specialists will be published by the Advisory Board for Medical Specialties.

Many national and local ophthalmologic societies demand the certificate of the American Board of Ophthalmology before admission. Promotion in many hospitals cannot be obtained unless the applicant holds the certificate of the board.

For sufficient reason, a person enrolled in this preparatory group may be dropped by vote of the board.

Communications should be addressed to the secretary-treasurer.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY, Inc.

WILLIS C. CAMPBELL, President, Memphis, Tenn.
PHILIP D. WILSON, Vice President, New York.
FREMONT A. CHANDLER, Secretary-Treasurer, 6 North Michigan Avenue, Chicago.

JOHN C. WILSON, Los Angeles.

INTRODUCTION

The rapid growth of specialism and the increasing number of physicians limiting themselves in their practice to one branch of medicine or surgery emphasize the need for the proper certification of specialists in the various branches of the

medical science. In recognition of this condition the American Board of Orthopaedic Surgery, Inc., aims to elevate the standard of qualifications for the practice of orthopaedic surgery and to certify those surgeons who voluntarily comply with its requirements.

In order to place orthopaedic surgery on the highest possible plane, the American Orthopaedic Association, the Section on Orthopaedic Surgery of the American Medical Association and the American Academy of Orthopaedic Surgeons united in organizing a certifying board which was incorporated in the year 1934 as the American Board of Orthopaedic Surgery, Inc.

The American Board of Orthopaedic Surgery, Inc., has been officially approved by the Advisory Board for Medical Specialties and by the Council on Medical Education and Hospitals of the American Medical Association.

WHAT THE BOARD WILL ACCOMPLISH

1. Certification by the board will establish a criterion to both interested lay and professional groups for judging the qualifications of an orthopaedic surgeon. Thus a reliable guide will be furnished for the choosing of consultants.

2. Hospitals and other organizations will no doubt establish rules limiting service on their permanent staffs to those certified by the board.

3. It will gradually tend to limit the practice of orthopaedic surgery to those properly qualified.

4. Certification by the American Board of Orthopaedic Surgery is one of the essential requirements for membership in the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons.

Excerpts from Articles 1, 2, 7 and 8 of the By-Laws.

Article 1. *Section 1. DEFINITION.* Orthopaedic Surgery is that branch of surgery especially concerned with the preservation and restoration of the functions of the skeletal system, its articulations and associated structures.

Article 2. *Section 2. PURPOSES.* To test and determine the qualifications of applicants for registration and to issue certificates to those found qualified.

Section 3. To prepare and maintain a registry of the holders of the certificates issued by the board.

Section 4. To serve the public, physicians, hospitals and medical schools by furnishing lists of those who have received the certificate of the Board, and thus to assist in protecting the public against irresponsible and unqualified practitioners who profess to specialize in orthopaedic surgery.

Article 7. *Section 1. APPLICATION FOR CERTIFICATE.* Each application for a certificate shall be filed with the secretary upon the prescribed form, and shall be accompanied by the fee which the board may fix from time to time. It shall also be accompanied by an unmounted autographed recent photograph of the applicant and the names of two orthopaedic surgeons acceptable to the board, who may be referred to for information in regard to the applicant.

Section 2. The applicant must have the following qualifications:

(a) He must be a graduate of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

(b) He must be of high ethical and professional standing.

(c) He must be a citizen of the United States or Canada.

(d) He must be duly authorized to practice medicine in the state or province of his residence.

(e) He must be a member of the American Medical Association or another society approved by the Council on Medical Education and Hospitals of the American Medical Association.

(f) He must have had one year of internship in a general hospital acceptable to the board.

(g) After Jan. 1, 1940, he must have had three years of concentrated instruction in orthopaedic surgery approved by and acceptable to the board. (A residency of at least two years on an orthopaedic service of a hospital recognized by the Council of the American Medical Association is desirable.)

(h) He must have knowledge of the basic medical sciences related to orthopaedic surgery.

(i) He must have had at least two years' further experience in the actual practice of orthopaedic surgery. Continuation of training (g) beyond the three years required will not be considered as actual practice unless the position of the candidate is considered permanent or his responsibilities equivalent to those encountered in private practice. This means that interns, residents, fellows, graduate students and assistants will not be

credited with additional periods of training unless they are permanent members of the organizations with which they are associated.

(j) He must have limited his work to the field of orthopaedic surgery for at least two years prior to the submission of his application for examination.

(k) In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the Council on Medical Education and Hospitals of the American Medical Association and to the National Board of Medical Examiners. In addition, he must have been engaged in the practice of orthopaedic surgery in the United States (or Canada) for at least three years prior to the submission of his application.

Section 3. Each applicant shall be examined and his qualifications determined by the board in such manner as it may designate, and his record shall be reviewed by the board in the light of all assembled information.

Article 8. Section 1. CERTIFICATE. If the applicant be found qualified therefor, a certificate that he has been found by this board qualified to practice orthopaedic surgery shall be issued to him. The certificate shall be in such form as may be adopted by the board, and shall be signed by the officers and members of the board.

EXAMINATION

Examinations will be held once or twice a year. If feasible, these examinations will be in conjunction with meetings of the major orthopaedic societies.

Oral and written examinations will be held on clinical, anatomical and pathological phases of orthopaedic surgery. Anatomical and pathological laboratories and hospital wards will be used when practicable.

APPLICATION FOR CERTIFICATION

Application forms may be obtained from the secretary of the board. These should be filled in accurately and returned not less than ninety days prior to the next examination. An autographed photograph and the fee must accompany the application.

FEES

A fee of \$50 must accompany the completed application form. This fee will be returned only in the cases of candidates found ineligible for examination. Address communications to the secretary-treasurer.

Communications should be addressed to the secretary-treasurer.

ORIGIN, AIMS AND METHODS

SOURCE OF AUTHORITY

In 1916 the American Academy of Ophthalmology and Otolaryngology appointed a committee on examinations, consisting of Drs. Thomas E. Carmody, Harris P. Mosher and Ross Hall Skillern, before whom new members professing otolaryngology as their sovereign work, were to appear to be qualified as such.

In 1924, through the persistent efforts of Dr. George Shambaugh, this activity was enlarged to include representatives from the American Otological Society; the American Laryngological Association; the American Laryngological, Rhinological and Otological Society; the American Academy of Ophthalmology and Otolaryngology; and the Section on Laryngology, Otology and Rhinology of the American Medical Association. Each organization appointed two members, making a total of ten, which constituted the first American Board of Otolaryngology.

Dr. T. H. Halsted of Syracuse, New York, and Dr. H. W. Loeb of St. Louis were appointed to represent the American Otological Society; Dr. H. P. Mosher of Boston and Dr. R. H. Skillern of Philadelphia were appointed to represent the American Laryngological Association; Dr. B. R. Shurly of Detroit and Dr. F. R. Spencer of Boulder, Colorado, to represent the American Laryngological, Rhinological and Otological Society; Dr. T. E. Carmody of Denver and Dr. W. P. Wherry of Omaha to represent the American Academy of Ophthalmology and Otolaryngology; and Dr. J. C. Beck of Chicago and Dr. R. C. Lynch of New Orleans to represent the Section on Laryngology, Otology and Rhinology of the American Medical Association.

CHIEF ACTIVITIES OF THE BOARD

First. To establish standards of fitness to practice otolaryngology.

Second. To arrange, control and conduct examinations to test the qualifications of those who desire to practice otolaryngology and to confer a certificate on those who meet the established standards.

These activities proceed from the object of the corporation which is stated in the Articles of Incorporation to be:

"The object of the corporation shall be to elevate the standard of otolaryngology, to familiarize the public with its aims and ideals, to protect the public against irresponsible and unqualified practitioners, to receive applications for examination in otolaryngology, to conduct examinations of applicants, to issue certificates of qualification in otolaryngology and to perform such duties as will advance the cause of otolaryngology."

NO DEGREES

The conferring of a degree is left to the universities, where it belongs, and the board makes no attempt to control the practice of otolaryngology by efforts to promote any license or legal regulation whatever. It simply aims to establish a standard of fitness to practice otolaryngology, and to certificate those who voluntarily apply and satisfy the board of their qualification.

VALUE OF CERTIFICATE

The five national otolaryngological associations responsible for the organization of the board are sponsoring its activities. Four of these associations require the board certificate from each applicant for membership.

Other important societies and organizations are following the example of these influential organizations. Moreover, the certificate of the board is required of candidates for appointments in many and various important positions in hospitals, colleges, etc. It is expected that the medical public and the lay public will learn to discriminate between those who are well fitted and those who are not, and will be influenced by the certificate of the board in arriving at their conclusions.

CLASSIFICATION OF CANDIDATES

Applicants for examination and for the certificate of the board are divided into classes according to the length of time they have practiced otolaryngology.

(Limited practice in otolaryngology interpreted as 90% otolaryngological practice—ophthalmology excepted.)

Class I—Limited Practice—15 years or more.

Class II—Limited Practice—10 to 15 years.

Class III—Limited Practice—5 to 10 years.

Class IVA—Limited Practice—5 years.

Class IVB—Limited Practice—3 and 4 years.

(Only candidates having completed a satisfactory residency or an acceptable full academic year basic science course are eligible to IVB.)

REQUIREMENTS
UNTIL JAN. 1, 1942

The following general requirements are demanded by the board:

First. A candidate acceptable for the examination must be a graduate from a school approved by the Council on Medical Education and Hospitals of the American Medical Association; furthermore, he must have at least one year of internship in an approved hospital.

Second. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies should not be required.

Third. In addition, a candidate must have completed at least three years graduate preparation for the specialty, at least one year (more desirably two) in a recognized residency or in basic courses and followed by private practice in otolaryngology.

Fourth. Five years of specialized practice will be accepted in lieu of the requirements of paragraph 3 until Jan. 1, 1942.

Fifth. Application must be made on a special blank procured from the secretary. It must be executed and returned to the secretary, together with other required credentials, sixty days in advance of the examination at which the candidate desires to appear.

Sixth. All applicants must send a small photograph with application and must present themselves in person before the board.

Seventh. Fee for the examination is \$50 and same must accompany application blank. No application will receive consideration until fee is paid.

Eighth. An application remains valid only five years—therefore, an applicant must appear for examination within this time or forfeit fee. The fee under no circumstances is returnable.

If the candidate fails in an examination he will be admitted to a second examination after one year, but within the regulation time limit of his application. Sixty days' notice of intention to appear is required. If a candidate who has failed does not appear before the expiration of validity of his application he will be required to make new application and pay additional fee of \$50 before reexamination.

An applicant having failed twice, must file a new application, pay an additional fee of \$50 and convince the board of additional postgraduate study previous to being assigned appointment for another examination.

Examinations covering two or three days will be held bi-annually at, or near, the time and place of meeting of the American Medical Association, and of the American Academy of Ophthalmology and Otolaryngology.

An extra examination is sometimes held provided the class of applicants is large enough to warrant it.

Candidates are required to sign the following pledge:

I hereby apply to the American Board of Otolaryngology for examination by the said board in accordance with its rules and herewith enclose the fee of fifty (\$50) dollars. I hereby agree that prior to an examination, or subsequent to my examination, the board may investigate my standing and reputation as a physician, including my reputation for complying with the standard of ethics of the profession, and may refuse to examine me, or, having examined me, may refuse a certificate, and such refusal to grant a certificate, whether justified or otherwise, may not and shall not be questioned by me in any court of law or equity or other tribunal, nor shall I have any claim, in the event of such refusal, to a return of the fee accompanying this application.

PRACTICAL EXAMINATION

- 1—Written examinations:
Class III, Class IVA and Class IVB.
 - 2—Pathology:
Microscopy—Class IVA, Class IVB.
Gross—Class III, Class IVA and IVB.
 - 3—Clinical examination of patients: To include history taking; physical and functional examinations; use of laboratory and x-ray findings; discussion of differential diagnosis; and discussion and defense of his findings, opinion and suggested management.
All classes.
 - 4—Didactic examination to be a private, oral examination covering any aspect of otolaryngology and its interrelation with general medicine.
All classes.
- Communications should be addressed to the secretary-treasurer.

AMERICAN BOARD OF PATHOLOGY, Inc.

A. H. SANFORD, President, Rochester, Minn.
FREDERICK H. LAMB, Vice President, Davenport, Iowa.
FRANK W. HARTMAN, Secretary-Treasurer, 2799 W. Grand Blvd., Detroit.
ALVIN G. FOORD, Pasadena, Calif.
N. CHANDLER FOOT, New York.
HOWARD T. KARSNER, Cleveland.
ROY R. KRACKE, Emory University, Ga.
JOSIAH J. MOORE, Chicago.

ORGANIZATION

In June 1935 the Section on Pathology and Physiology of the American Medical Association and the American Society of Clinical Pathologists appointed committees which acted jointly in consideration of the feasibility and necessity of a national qualifying board. The joint committees agreed unanimously that such a board should be established and proceeded to draw up by-laws for such a board. In May 1936 the American Society of Clinical Pathologists and the Section on Pathology and Physiology of the American Medical Association accepted the proposed by-laws, authorized the nomination of four members each to the board and suggested incorporation in the state of Michigan. Approval of the board by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association was given. On July 19, 1936, the organization of the board was carried out in Chicago.

The officers of the board who were elected at this meeting, were:

A. H. Sanford, President.
Frederick H. Lamb, Vice President.
F. W. Hartman, Secretary-Treasurer.

Drs. Hartman and Moore of the A. M. A. Section and Drs. Sanford and Lamb of the A. S. C. P., whose terms on the board expired in 1940, were renominated by their respective organizations and were reelected by the board. The president, vice president and secretary-treasurer were also reelected for 1940-1941.

PURPOSES

A. To encourage the study and promote the practice of pathology.

B. To elevate the standards and advance the cause of pathology, by encouraging its study and improving its practice.

C. To determine the competence of those wishing to practice this specialty of pathology and to arrange, conduct, and control investigations and examinations to determine the qualifications of such individuals who voluntarily apply for the certificates issued by the corporation.

D. To grant and issue certificates in the special field of pathology to voluntary applicants therefor and to maintain a registry of holders of such certificates.

E. To serve the public, the medical profession, hospitals, and medical schools by preparing and furnishing lists of specialists who have been certified by the corporation.

VALUE OF THE CERTIFICATE

Judging from the experience of other specialties operating a certifying board it is anticipated that the certificate will be of value in that the medical profession, the lay public, and hospital administrators will utilize certificates from the board as a means of discriminating between those that are thoroughly qualified in pathology and those that are not. Lists of those holding certificates will be made available from time to time by this board through the publication of the same in pamphlets and in national medical journals.

BOARD NOT AN EDUCATIONAL INSTITUTION

The board is in no sense an educational institution and the certificates of the board are not to be considered degrees. Therefore the certificate does not confer on any person legal qualifications, privileges, or license to practice medicine or the specialty of pathology. The board does not purport in any way to interfere with or limit the professional activities of any licensed physician. Its chief aim, as stated above, is to standardize the qualifications for the specialty of pathology and to issue certificates to those voluntarily complying with the requirements of the board.

GENERAL REQUIREMENTS

- A. General qualifications.
 1. Satisfactory moral and ethical standing in the profession.
 2. License to practice medicine.
 3. Membership or associate membership in the American Medical Association or by courtesy membership in such Canadian or other national medical societies as are approved by the Council on Medical Education and Hospitals of the American Medical Association.
 4. That the applicant devotes his time primarily and principally to the practice of pathology.

B. Professional education.*

1. Graduation from a medical school in the United States or Canada, approved by the Council on Medical Education and Hospitals of the American Medical Association.

C. Special training, to be effective after July 1, 1938:

1. Completion of an internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. A period of study, exclusive of internship, of not less than three calendar years, exclusive of reasonable vacation periods, in an institution or department of pathology recognized by the same Council and the Board of Trustees as competent to provide a satisfactory training in the field of pathology. This period of special training preparation shall include the following:

- (a) Graduate training for one year in the various phases of clinical pathology.

- (b) Training and experience of not less than two years in a department of pathologic anatomy.

- (c) Such training may be combined or in sequence.

3. A fifth year of training or practice in pathology.

D. Special qualifications:

1. The board may accept candidates without special training as outlined in Section C above provided that:

- (a) The candidate shall have been for a period of five years of professorial rank in a department of pathology in an approved medical school, or

- (b) The candidate shall have been practicing pathology for ten years in a senior position in a hospital, having an adequate department of pathology, and approved by the Council on Medical Education and Hospitals of the American Medical Association.

Candidates with special qualifications, as outlined in Section D above, may be certified without examination, at the discretion of the board.

APPLICATION BLANK AND FEE

Application must be made on the special form which may be procured from the secretary and forwarded with other required credentials and the application fee. Applications cannot be given consideration by the board unless accompanied by the application fee.

The application or examination fee for candidates is \$35. If certified without examination \$10 of fee will be refunded. If the candidate fails in his examination he will be admitted to a second examination after one year, but not later than three years, without additional fee. After two reexaminations the applicant must file a new application and pay an additional fee before a fourth examination will be given.

The examination fee of \$35 has been arrived at after careful consideration, and is based on actual estimates of the expense of examination and administration. None of the board members receive any compensation for their services except actual expenses incurred.

If the applicant, for any reason, is deemed ineligible for examination by the board his fee will be returned; however, the application fee is not returnable after the candidate has officially been accepted for examination and notified to report for the same.

EXAMINATIONS

Written and oral examinations will be held at or near the time and place of national medical meetings at the discretion of the board. If a number of applications from any region of the country are received an examination in conjunction with a national medical meeting in that section will be arranged so that the financial outlay of the applicant in meeting the examinations will be as small as possible.

The examinations are to be based on the broad principles of pathology with emphasis on diagnosis and interpretation. The

* NOTE: In case of an applicant whose education and/or training has been received outside the United States or Canada, his credentials must be acceptable to the National Board of Medical Examiners and the American Board of Pathology.

applicant may apply for certification in either pathologic anatomy or clinical pathology, or both. These general subjects have been defined in the by-laws as follows:

1. Pathologic anatomy is that branch of pathology which deals with the morphological aspects of disease, recognition being given that this definition covers two phases of pathology.

- (a) The applied phase, with special attention to biopsy description and diagnosis.

- (b) The academic phase of teaching and general morphological diagnosis.

2. Clinical pathology is that branch of pathology which deals with bacteriology, immunology, biochemistry, parasitology, hematology, and clinical microscopy, in relation to the diagnosis, prognosis, and treatment of clinical disease.

All communications should be addressed to the secretary-treasurer.

ORIGIN

The American Board of Pediatrics was established in June 1933 by joint action of the American Pediatric Society, the American Academy of Pediatrics and the Section on Pediatrics of the American Medical Association after consideration of the report of a committee on pediatrics as a special field of medical practice. The committee recommended that the certification plan adopted and in use in the fields of ophthalmology, otolaryngology, gynecology and obstetrics, and dermatology be adapted to pediatrics. Similar boards have been subsequently formed in all the other special fields.

In order to correlate the activities of the various qualifying boards there has been formed the Advisory Board on Medical Specialties, composed of representatives of all the qualifying boards, including the American Board of Pediatrics, as well as representatives of the Association of American Medical Colleges, the National Board of Medical Examiners, the Federation of State Medical Boards of the U. S. A. and the American Hospital Association.

Any method of certification in any specialty must be national in scope, must in its ultimate analysis be controlled by the men in each special field and must be independent of society membership or affiliation. The American Board of Pediatrics fulfills these three essentials: A uniform standard of competency is set up, the character of which is assured through the affiliation with the Advisory Board on Medical Specialties; the board is controlled by pediatricians, its membership being composed of three men appointed by each of the three national pediatric societies; the board is not a medical society, however, and certification is independent of society affiliation.

FUNCTION

The functions of the board are outlined in the articles of incorporation as follows:

"To encourage the study, improve the practice and elevate the standards of pediatrics; and to grant and issue to physicians, duly licensed by law, certificates or other equivalent recognition of special knowledge in pediatrics."

The board has interpreted this to mean that its efforts to encourage and improve the practice of pediatrics shall be limited to its function of certification of competency in the specialty. Obviously other organizations are better able to further the general improvements in pediatrics.

The board specifically defines its activities as follows:

1. To establish standards by which the competency of men to practice pediatrics may be estimated.

2. To arrange, control and conduct examinations to test the qualifications of those desiring certification as pediatricians.

3. To grant certificates of qualification to those applicants who meet the standards successfully.

The board further feels that in carrying out these activities it is merely acting as the agent of the three societies which appointed its members and initiated the project.

No financial recompense of any kind is made to any member of this board except to cover actual traveling expenses to meet-

ings and examinations. The \$30 fee is fixed below that of any of the similar examining boards of other specialties. In the light of experience of the existing boards it may later be necessary to raise this fee to carry on the work of the board successfully.

CERTIFICATE—NOT A DEGREE

Certificates granted are in no sense degrees, nor do they purport to confer upon any person any legal qualification, privilege or license to practice pediatrics. Neither does the board intend in any way to limit the activities of any licensed physicians. It is merely attempting to standardize qualifications and to issue certificates to those who voluntarily comply with the requirements.

VALUE OF THE CERTIFICATE

It is anticipated that the certificate will become of value in that both the medical and lay public, including hospital directors, will soon utilize the certificate from this board as a means of discriminating between those who are well grounded as pediatricians and those who are not.

A certificate is required as one of the qualifications for new members of the American Academy of Pediatrics. The certificate of the American Board of Pediatrics is recognized by the Council on Medical Education of the American Medical Association. Holders of certificates are so designated in the directory of the American Medical Association.

Lists of those holding certificates will be published by this board from time to time. Such lists will also be published in the leading pediatric journals of the country.

APPLICANTS FOR CERTIFICATES

Requirements for Applicants.—Each applicant for a certificate must establish in a manner satisfactory to the board that he is of high ethical and professional standing, is a graduate of a medical school which is satisfactory to the board, and has received adequate training in pediatrics as a specialty in addition to passing the examination given by this board.

Applicants must be citizens of the United States, of its dependencies, or of Canada.

Applicants will be divided into two classes, according to the length of time they have been engaged in the specialty.

Following is the classification of applicants for certification. The changes are based upon the experience gained from examination and upon the general requirements as adopted by the Advisory Board of Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

Group I.—Physicians who have specialized in pediatrics for ten years or more. After July 1, 1943, Group I will be abolished.

The minimum requirements for *Group II* are as follows: Graduate of a Class A medical school.

One year's intern service in a recognized hospital.

Two years' service in a pediatric center.*

An additional term of two years of specialized study and/or practice.

The board defines service in a pediatric center as full time devoted to rounded experience in an acceptable hospital or a graduate course, which includes ward and outpatient service and both therapeutic and preventive pediatrics. The time served in pediatric centers need not be continuous or spent in the same institution. In the case of a post-graduate course an academic year will meet the requirement of one year's work.

The application fee is \$30 and must be remitted with the application. Refund will be made only if the applicant is refused examination. The applicant who has failed in an examination will not be required to pay a second fee if he takes another examination after the lapse of two years.

Application must be made on special blanks which may be secured from the secretary. These must be sent to the secretary at least four months before the date at which the candidate expects to take the examinations.

Letters from two competent pediatricians recommending each applicant must be sent to the secretary of the board. These letters are not to accompany the application, but should be sent directly to the secretary. No member of the board may recommend any applicant.

INFORMATION CONCERNING EXAMINATIONS

Examinations will be held at or near the time and place of meetings of the American Medical Association and of the American Academy of Pediatrics, or at other times and places at the discretion of the board, depending on the number of applicants from any region of the country. It is proposed to arrange examinations in different cities so that as little financial burden as possible will be placed upon the applicants in meeting the examiners.

* A maximum of six months of this time may be spent in full time contagious work in a recognized hospital.

The purpose of these examinations is to determine the applicant's competency to practice pediatrics. This board feels that the best impression of an applicant's ability can be obtained by oral examination although written ones may be substituted at times. It is not proposed at the present time to require the applicant to send in case reports. The board feels that growth and development are fundamental parts of pediatric training.†

A list of papers or books published must be sent with the application blank.

Further information as to the scope of the examinations will be published as soon as available. It should be emphasized that competency in the practice rather than in the theory of pediatrics is required.

Communications should be addressed to the secretary.

HISTORY AND STATEMENT OF PRINCIPLES

The American Board of Psychiatry and Neurology was founded in 1934 following conferences of committees appointed by the American Psychiatric Association, the American Neurological Association, and the Section on Nervous and Mental Diseases of the American Medical Association. This action was taken in response to a widespread desire among specialists in psychiatry and neurology for some means of distinguishing the fully qualified specialist from the would-be specialist of inferior training and inadequate experience. That this desire is by no means limited to those who practice psychiatry and neurology is indicated by the formation of corresponding boards covering internal medicine, surgery, and the major specialties. The success of this method of distinguishing the specialists is indicated by the increasing number of candidates taking the examinations, and by the listing accorded in the American Medical Directory to those specialists holding the certificates of the various boards.

CONSTITUTION AND ACTIVITIES

The American Board of Psychiatry and Neurology is composed of twelve members, four each from the American Neurological Association and from the American Psychiatric Association and two neurologists and two psychiatrists elected by the Section on Nervous and Mental Diseases of the American Medical Association. Annual elections to fill the places of members whose terms have expired take place in each of the nominating associations with the understanding that neurology and psychiatry are always equally represented on the board. The board holds annual meetings in December of each year for the transaction of whatever business may come before it and also holds special meetings for the purpose of examining candidates and of passing upon the qualifications of those seeking the certificate without examination.

FUNCTIONS

(a) To determine the competence of specialists in psychiatry and neurology.

(b) To arrange, control and conduct investigations and examinations to test the qualifications of voluntary candidates for certificates issued by the board.

(c) To grant and issue certificates or other recognition of special knowledge in the field of psychiatry and neurology to successful voluntary applicants therefor.

(d) To serve the public, physicians, hospitals and medical schools by preparing lists of practitioners who shall have been certified by the board.

(e) To consider and advise as to any course of study and technical training, and to diffuse any information calculated to promote and ensure the fitness of persons desirous of qualifying for a certificate of qualification to be issued thereby.

† The three volumes on Growth and Development of the White House Conference contain this material. Century Company, publishers.

INFORMATION FOR APPLICANTS
EXCERPTS FROM ARTICLE VII OF THE BY-LAWS

SECTION 1. Application for Certificates. Application for certificates shall be considered by the secretary only when made formally on the official application blank in such form as may be adopted from time to time by the board of directors and when accompanied by an application fee in such amount as may be fixed from time to time by the board of directors.

SECTION 2. Form of Certificates. There shall be separate certification in psychiatry and in neurology and two certifications or a combined certification for those qualified in both fields. The certificates shall be in such form as is approved by the board of directors.

SECTION 3. Requirements for Applicants. Each applicant for a certificate must establish that—

(a) He is a physician duly licensed by law to practice medicine.

(b) He is of satisfactory ethical and professional standing.

(c) He is now a member of the American Medical Association, or a member of such medical societies as are recognized for purposes of certification by the Council on Medical Education and Hospitals of the American Medical Association. Exceptions to the foregoing may be made at the discretion of the board for good and sufficient reasons.

(d) He has received adequate training in psychiatry or neurology, or both, as a specialty.

SECTION 4. No candidate is eligible for examination by the board until he has completed at least five years of special training and experience in neurology or psychiatry for a single certificate, or at least six years of training and experience for certification in both neurology and psychiatry.

CLASSES OF APPLICANTS AND FEES

Applicants may request certification in psychiatry, or in neurology, or in both psychiatry and neurology.

Limitation of practice to the specialty of psychiatry and/or neurology need not be complete provided a candidate both by his previous training, experience and standing, and by examination, can prove his competency to practice that specialty.

However, in case a physician has already been certified by one of the other boards as a specialist in another field, he will not be considered for certification in psychiatry and/or neurology except under special circumstances.

Class I

Physicians who graduated from medical school in 1919 or before and who have carried on specialized practice in neurology and/or psychiatry for at least fifteen years are to be considered on their professional record and passed, if satisfactory to the Board, or further evidence of qualification or examination may be required.

A candidate in Class I who has received certification in either psychiatry or neurology may apply within three years for certification in the other field without additional fee. After three years such application shall be considered as a new application with corresponding fees.

When certification in Class I has been refused, the candidate may file application for reconsideration within three years without additional fee. After three years such application for reconsideration shall be considered as a new application with corresponding fees.

Class II

Physicians who graduated from medical school up to and including 1929 and who have practiced the specialty of psychiatry and/or neurology for at least five years will be required to pass an examination in psychiatry or neurology, or both.

Class III

Physicians who graduated after 1929, up to and including 1934, will be required to pass an examination to satisfy the board that they have adequate knowledge of all subjects specified in the by-laws for candidates graduating after 1934. Their previous training and experience must be acceptable to the board.

Class IV

Candidates graduating from medical school after 1934 shall fulfil the preceding general requirements as given in Section 3 of Article VII and the following special requirements:

PROFESSIONAL EDUCATION

(1) Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

(2) Completion of a general internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

(These requirements are to be placed in force as soon as practicable after Jan. 1, 1940. In the meantime a syllabus covering the knowledge required of the candidate has been prepared and is available to those who request it.)

Admission to the examination for certification in neurology or psychiatry requires a total experience of not less than five years. This period shall include the following:

1. A period of study, after the general internship, of not less than three full years in institutes, hospitals, clinics, dispensaries, laboratories, and other institutions recognized by the Council of the American Medical Association and approved by the American Board of Psychiatry and Neurology as competent to provide a satisfactory training in psychiatry and/or neurology.

(a) As subject matter,

Neuro-anatomy	Psychobiology
Neurophysiology	Psychopathology
Neuropathology	Neuro-röntgenology
Clinical neurology	Clinical psychiatry

and other basic medical sciences, which, in the opinion of this board, are necessary to the proper understanding and treatment of psychiatric and/or neurologic disorders.

2. An additional period of not less than two years of practice in psychiatry and/or neurology.

3. Candidates wishing to be admitted to the examinations for certification in both fields must have had a minimum of six years of experience in both fields.

PAYMENT OF FEES

The candidate on filing his application shall accompany it with an application fee of \$25. When notified by the Secretary that he is eligible for examination he shall send the examination fee of \$25 to the secretary at least two weeks before the date of the examination. The certification fee of \$25 is payable upon notification by the board that certification has been awarded the candidate in Class I on his record. No fees will be returned.

The same examination is given whether a candidate applies for certification in psychiatry, or in neurology, or in both psychiatry and neurology. The board requires some proficiency in neurology on the part of those it certifies in psychiatry and vice versa, but judges the candidate in accordance with the certificate he seeks.

Should a candidate receive certification in either psychiatry or neurology, he may apply within three years for partial examination for the certificate in the complementary subject, upon payment of a complementary examination fee of \$10. After three years, the second application shall be considered a new application, with corresponding \$25 fees.

EXAMINATIONS

Date and places of examination are set by the board at its discretion and are announced in *The Journal of the American Medical Association*, in the *American Journal of Psychiatry*, in the *Journal of Nervous and Mental Disease*, and in the *Archives of Neurology and Psychiatry*.

The examinations are designed to test the ability of the candidates to meet the situations in which they might at any time be called upon as specialists to assume responsibility. They will be of such a type that no adequately trained individual will fail, yet they will be sufficiently searching so that the specialist-in-fact will be separated from the specialist-in-name. Each candidate is required to identify and to discuss the function of the more important anatomic structures in the brain and spinal cord, to discuss gross and microscopic pathologic specimens and to interpret roentgenograms dealing with neurologic disorders. He is examined orally on the subjects of psychobiology and psychopathology. These examinations in the preclinical subjects usually last about two hours. Each candidate examines two patients with neurologic disorders and two with psychiatric disorders, and discusses with the examiners the various problems involved. One hour, on the average, is allotted to each of these four clinical examinations. The manner of examining both neurologic and psychiatric patients and the reasoning and deductions therefrom constitute the most important part of the examination. Some acquaintance with the history of psychiatry and neurology, with the body of doctrine, and with the recent advances, is presupposed.

REEXAMINATIONS

A candidate who has failed in one examination is eligible to reexamination in the whole subject, within three years, on payment of a reexamination fee of \$10. A candidate who has failed in one examination and who does not apply for reexamination within three years or a person who has applied within that time but who has failed a second time will be considered

a new applicant, with corresponding \$25 fees. The \$10 reexamination fee also applies to candidates conditioned in one or more subjects at any time within three years of the first examination, and is payable before each reexamination.

HANDLING OF APPLICATIONS

An application, in order to be considered at any meeting, must be in the hands of the secretary of the board not less than seventy days before the date of such meeting.

The secretary of the board on receipt of an application shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary may deem desirable and shall verify the candidate's record from the biographical records of the American Medical Association, after which he shall forward the application to the committee on credentials. This committee shall consider the application and other information available and notify the secretary whether the application is accepted. The certification of a candidate in either psychiatry or neurology, or both, shall be approved by a majority of the members of the entire Board at any meeting held for such certification.

PLEDGE

Each candidate is required to sign the following pledge:

"I hereby make application to the American Board of Psychiatry and Neurology, Incorporated, for the issuance to me of a certificate of qualification as a specialist in (a) Psychiatry; (b) Neurology; (c) Psychiatry and Neurology (check the one desired) and for examination relative thereto, all in accordance with and subject to its rules and regulations. Upon the issuance of the certificate I agree to and do become bound by the by-laws of the American Board of Psychiatry and Neurology, Inc., insofar as applicable.

"I agree to disqualification from examination or from the issuance of a certificate of qualification or to forfeiture and redelivery of such certificate of qualification in the event that any of the rules governing such examination are violated by me or for any one of the reasons set forth in the by-laws. I agree to hold said American Board of Psychiatry and Neurology, Inc., its members, examiners, officers and agents, free from any damage or claim for damage or complaint by reason of any action they, or any of them, may take in connection with this application, such examination, the grade or grades given with respect to any examination, and/or the failure of said corporation to issue to me such certificate of qualification."

RULES AND REGULATIONS

(ART. VII, SEC. 5, OF THE BY-LAWS)

The board of directors, from time to time, by resolution adopted by the affirmative vote of a majority then in office, may adopt, amend and repeal rules and regulations respecting requirements of applicants, the nature and extent of examinations and investigations and issuance of certificates.

REVOCATION OF CERTIFICATES

(ART. VII, SEC. 6, OF THE BY-LAWS)

All certificates issued by the corporation shall be issued subject to the provisions of the certificate of incorporation and of the by-laws of the American Board of Psychiatry and Neurology, Inc. Each such certificate shall be subject to revocation in the event that:

(a) The issuance of such certificate or its receipt by the physician shall have been contrary to or in violation of any of the provisions of the corporation's certificate of incorporation or by-laws; or

(b) The physician so certified shall not have been eligible in fact to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to any or all of the directors of the corporation or could have been ascertained by any or all of the directors of the corporation at the time of the issuance of such certificate; or

(c) The physician so certified shall have made any deliberate misstatement of fact in his application for such certificate or in any other statement or representation to the corporation, its directors, representatives or agents; or

(d) The physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the board of directors of the corporation, moral turpitude in connection with his practice of medicine; or

(e) The physician so certified shall have had his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

FORM OF CERTIFICATE

The secretary shall have prepared subject to the approval of the board members a form of certificate containing the following wording:

THE AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC.

This is to certify that.....has satisfied the requirements of the board and is hereby certified as qualified to practice the specialty of Psychiatry and/or Neurology.

(Signed) President.....
Vice President.....
Secretary

HISTORY AND AUTHORITY FOR ORGANIZATION

The medical profession has long felt that there should be a standard of minimal requirements for the practice of any specialty in medicine in order to protect the public, the profession in general, and the specialists themselves. Some of the states have attempted by statute to prescribe such requirements in certain branches. Unless a better method of regulation were found, the other states would be likely to enact similar laws. The result would be forty-eight different standards for each of the many medical specialties. Obviously, a more practicable solution would be for each special group to put its own house in order and place its mark of approval on those qualified to practice as specialists in that particular field. Accordingly, in 1932, five nation-wide radiologic organizations, the Section on Radiology of the American Medical Association, the American Roentgen Ray Society, the Radiological Society of North America, the American College of Radiology, and the American Radium Society, each appointed a committee of three members to confer and investigate the feasibility of establishing a qualifying board. The following men were appointed by these five organizations: Drs. G. W. Holmes, J. W. Pierson, E. L. Jenkinson, W. E. Chamberlain, E. C. Ernst, W. F. Manges, L. R. Sante, L. C. Kinney, A. C. Christie, Albert Soiland, W. W. Wasson, Henry Schmitz, Lester Hollander, Rollin H. Stevens and B. R. Kirklin.

This combined committee met at Milwaukee in 1933, during the meeting of the American Medical Association, agreed unanimously that such a board should be established and so reported to the respective organizations. Each of the organizations approved the report, appointed three representatives, and empowered them to proceed to the formation of a national radiologic board. The members of the board thus chosen were: Drs. W. F. Manges, L. R. Sante and B. R. Kirklin, representing the American Roentgen Ray Society; Drs. A. C. Christie, E. C. Ernst and E. L. Jenkinson (succeeding Dr. Byron H. Jackson, originally appointed) representing the American College of Radiology; Drs. R. H. Stevens, Henry Schmitz and H. K. Pancoast, representing the American Radium Society; Drs. L. J. Menville, M. C. Sosman and Albert Soiland, representing the Radiological Society of North America, and Drs. L. C. Kinney, J. W. Pierson and G. W. Holmes, representing the Section on Radiology of the American Medical Association.

The board was incorporated, organized and held its first meeting in Washington, D. C., in May 1934; at that time the by-laws were adopted and provision was made by resolution for its proper function. The officers of the board elected at this meeting were:

Dr. H. K. Pancoast, President.

Dr. A. C. Christie, Vice President

Dr. B. R. Kirklin, Secretary-Treasurer.

This move put into action the determined effort on the part of these five national organizations to improve the standards of the practice of radiology. It expects to accomplish this by various activities, such as the investigation and encouragement

of facilities for graduate extension study and active clinical assistantships for men desiring to specialize in radiology; it will endeavor by regular examinations to determine the competence of specialists in radiology who apply for the certificate.

During 1935 the American Board of Radiology was accepted for membership in the Advisory Board for Medical Specialties and was also approved by the Council on Medical Education and Hospitals of the American Medical Association. Hereafter the list of Diplomates of the Board will take the place of the Council's list of approved radiologists, and the latter list will be discontinued.

PURPOSES

First: To encourage the study and promote and regulate the practice of radiology.

Second: To elevate the standards and advance the cause of radiology by encouraging its study and improving its practice.

Third: To determine the competence of specialists in radiology; to arrange, control and conduct investigations and examinations; and to test the qualifications of voluntary candidates for certificates to be issued by the board.

Fourth: To serve the public, physicians, hospitals and medical schools by preparing lists of practitioners who shall have been certified by the board.

VALUE OF CERTIFICATE

The national radiologic organizations which have participated in the formation of the board and are sponsoring its activities, as well as other organizations, attach considerable importance to its certificate. It is expected that both the medical and the lay public, including hospital directors, will soon come to utilize the certificate from this board as a means of discriminating between those who are well grounded as specialists in radiology and those who are not.

To this end lists of those holding certificates from this board will be published and issued from time to time by the board. Similar lists will be published by the *American Journal of Roentgenology and Radium Therapy*, *Radiology*, and *The Journal of the American Medical Association*. The Directory of the American Medical Association will indicate by a numerical symbol in the biographic data of those whose names are eligible to appear on these lists that they are diplomates of this board.

For emphasis it is repeated that the board does not intend in any way to interfere with or limit the professional activities of any duly licensed physician, but it does aim toward standardized qualifications for those who claim to be specialists in radiology.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in radiology and has successfully fulfilled the requirements of the board.

A certificate granted by this board does not of itself confer, or purport to confer, any degree, or legal qualifications, privileges, or license to practice radiology. Certificates of the board shall be issued upon one of two forms:

1. A certificate to the effect that the applicant has been found qualified to practice radiology in all its branches.

2. A certificate to the effect that the applicant has been found qualified to practice radiology in one or more of the following special fields: (a) roentgenology; (b) diagnostic roentgenology; (c) therapeutic radiology.

DEFINITIONS

For the purposes of this board, the following definitions are adopted:

1. Radiology is that branch of medicine which deals with the diagnostic and therapeutic application of radiant energy including roentgen rays and radium.

2. Roentgenology is that branch of radiology which deals with diagnostic and therapeutic application of roentgen rays.

3. Diagnostic roentgenology is that branch of radiology which deals with the diagnostic application of roentgen rays.

4. Therapeutic radiology is that branch of radiology which deals with the therapeutic application of roentgen rays and radium.

GENERAL REQUIREMENTS

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

(A) General Qualifications.*

(1) Satisfactory moral and ethical standing in the profession.

(2) A license to practice medicine.

* NOTE: In case of an applicant whose training has been received outside of the United States and Canada, the credentials must be satisfactory to the Advisory Board for Medical Specialties.

(3) Membership in the American Medical Association, or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

(4) That the applicant holds himself out to be a specialist in radiology or one of its branches as defined under definitions, and that he uses roentgen rays or roentgen rays and radium either personally or under his direct supervision in a substantial portion of his practice.

(B) Professional Education.*

(1) Graduation from a medical school of the United States or Canada, recognized by the Council on Medical Education and Hospitals of the American Medical Association.

(2) Completion of an internship of not less than one year in a hospital approved by the same council.

(3) Three years' training in radiology or sufficient experience in lieu thereof.

(C) Special Training.* (To be effective Jan. 1, 1942.)

(1) A period of study after the internship of not less than three calendar years in an institution or radiologic department recognized by the same council and the board as competent to provide a satisfactory training in the field of radiology.

(2) This period of specialized preparation shall include:
(a) Graduate training in pathologic anatomy, radiophysics, and radiobiology.

(b) An active experience of not less than twenty-four months in a radiologic department recognized by the board and the council as capable of providing satisfactory training.

(c) Examination in the basic sciences of radiology as well as in the clinical aspects thereof.

APPLICATIONS

The board desires to appraise the candidate's educational opportunities (premedical, medical and radiologic), the ability of his instructors, his hospital and teaching positions, his original investigations, his contributions to radiologic literature, his membership in medical societies, and his local and general reputation.

For this purpose, application must be made on a special blank which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application shall be forwarded with the required data, two unmounted photographs, and the fee of \$35, at least two months before the date of the examination.

FEE

A fee of \$35 must accompany each application blank. This fee will not be returned and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. Members of the board and special examiners do not receive any compensation except for actual expenses connected with holding the examinations. As the number of candidates decreases, it may become necessary to raise the fee.

Checks should be made payable to the American Board of Radiology.

EXAMINATIONS

Each year the board will hold an examination in conjunction with the annual meeting of the American Medical Association, and, when sufficient applications are on file, a second examination will be held in conjunction with the annual meeting of the American Roentgen Ray Society and/or the Radiological Society of North America.

For the present, examinations consist of practical and oral examinations, although written examinations may be added later. The examinations are designed to test the candidate's fitness to practice radiology or one of its branches as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of the basic sciences of radiology, and likewise his knowledge of the recent literature on radiology, and his general qualifications as a specialist in this branch of medicine.

The examination consists of tests in film interpretation and an oral examination in pathology, physiology, radiophysics and radiobiology, as well as the clinical applications of roentgen rays and radium. The applicant is also examined in "professional adaptability," in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming his deficiencies.

REEXAMINATIONS

If the candidate fails in an examination he will be admitted to a second examination after one year has elapsed but not more than three years. He must give sixty days' notice of his intention to appear for reexamination and pay an additional fee of \$15. If a candidate who has failed does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$35.

A candidate having failed twice must file a new application and pay an additional fee of \$35.

FINAL ACTION OF THE BOARD

The final action of the board is based on the applicant's professional record, training, and attainments in the field of radiology, as well as on the results of his examination. Any radiologist who is practicing radiology honorably and efficiently should have no difficulty in obtaining a certificate. This board has been organized, not to prevent qualified radiologists from obtaining certificates, but to assist them in becoming recognized in their communities as men competent to practice in the special field of radiology.

REVOCATION OF CERTIFICATES

Certificates issued by this board are subject to the provisions of the Articles of Incorporation and the By-Laws. According to Article IX, Section 4, of the By-Laws "Any certificate issued by the Board of Trustees shall be subject to revocation in the event that:

(a) The issuance of such certificate or its receipt by the physician so certified shall have been contrary to or in violation of any provision of the Certificate of Incorporation of this the American Board of Radiology or of these by-laws; or

(b) The physician or party so certified shall not have been eligible in fact to receive such certificate; or

(c) The physician or party so certified shall have made any mis-statement of fact in his application or in any other communication to the board or its representatives; or

(d) The physician or party so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the Board of Trustees, moral turpitude; or

(e) If the physician or party so certified shall have had his license to practice medicine revoked or shall have been expelled from one of the societies or organizations which is represented by this corporation through eligibility of such society or organization to nominate and appoint members of this corporation."

Communications should be addressed to the secretary.

AMERICAN BOARD OF SURGERY, Inc.

EVARTS A. GRAHAM, Chairman, St. Louis.

ALLEN O. WHIPPLE, Vice Chairman, New York.

J. STEWART RODMAN, Secretary-Treasurer, 225 South Fifteenth St., Philadelphia.

HOWARD M. CLUTE, Boston.

ARTHUR W. ELTING, Albany, N. Y.

DONALD GUTHRIE, Sayre, Pa.

THOMAS M. JOYCE, Portland, Ore.

THOMAS G. ORR, Kansas City, Kan.

ROBERT L. PAYNE, Norfolk, Va.

FRED W. RANKIN, Lexington, Ky.

ERWIN R. SCHMIDT, Madison, Wis.

HARVEY B. STONE, Baltimore.

PHILEMON E. TRUESDALE, Fall River, Mass.

HISTORY

The organization of the American Board of Surgery was completed on Jan. 9, 1937. A plan for this organization had been carefully studied by a general committee representative of certain general and sectional surgical societies called together through the initiative of the American Surgical Association. As a result of the deliberations of this general committee a tentative plan of organization was adopted. This plan was reported to the cooperating surgical societies and was approved with the understanding that the board, when organized, would have the power to change or modify the proposed plan as it

saw fit. This board has been created in accordance with the action of the Advisory Board for Medical Specialties as approved by the Council on Medical Education of the A. M. A., which has named twelve specialty fields as being suitable to be represented by such boards. These boards have the two-fold purpose of certifying those found to be qualified after meeting reasonable requirements, and of improving existing opportunities for the training of specialists within the field concerned. This is to be done for the protection of the public and the good of the specialty.

PERSONNEL

* The cooperating surgical societies selected jointly to form the board appointed their representatives as follows:

The American Surgical Association.....	3
The Surgical Section of the A. M. A.....	3
The American College of Surgeons.....	3
The Southern Surgical Association.....	1
The Western Surgical Association.....	1
The Pacific Coast Surgical Association.....	1
The New England Surgical Society.....	1

13

The term of membership is for six years. Each cooperating association has the appointing power of its representatives subject to the approval of the board.

PURPOSES

(a) To conduct examinations of satisfactory candidates who seek qualification by the Board.

(b) To issue certificates of qualifications to all those meeting the board's requirements.

(c) To improve the opportunities for the training of the surgeon.

REQUIREMENTS

(A) GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession satisfactory to the board.

The board, believing that the practice of "fee splitting" is pernicious, leading as it does to a traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

2. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the A. M. A. Except as here provided, membership in other societies shall not be required.

3. Those who have limited their activities to the practice of surgery.

4. In exceptional instances the board may, in its discretion, accept for examination candidates who have met all preliminary requirements and have been in practice from six to sixteen years but whose formal training does not comply with the full requirements to be exacted in the future.

The board recognizes two groups of candidates who may be eligible for certification.

(A) The Founders Group—those who have already amply demonstrated their fitness as trained specialists in surgery. Application for membership in this group will be open until January 9, 1940. Those who receive the board's approval will be accepted for membership without examination from the following:

1. Those who from the time of the board's organization, January 9, 1937, hold the position of Professor or Associate Professor of Surgery in the approved medical schools of the United States or Canada.

2. Those who for fifteen years prior to the board's organization have limited their practice to surgery and have met the general qualifications required.

3. Such members of the cooperating societies represented on the board, in good standing January 9, 1937, who may be invited to membership in this group.

This group was closed January 1, 1940; no further applications received.

(B) Qualified by examinations—

In addition to the general qualifications the requirements for this group shall be as follows:

(B) PROFESSIONAL STANDING

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education

* The first three of these associations being national in scope, were allotted three representatives each, the remaining associations, one.

and Hospitals of the A. M. A., or graduation from an approved foreign school.

2. Completion of an internship of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the board. This internship may be rotating or one devoted to a single branch of medicine as, for example, surgery, medicine, pathology, etc.

(C) SPECIAL TRAINING

After the completion of the year's internship there shall be a period of special training in surgery of not less than five years. During this period one's entire time must be devoted to surgical training supplemented by sufficient experience in the basic sciences to comply with the provisions of Paragraph 2. Such training may be taken in a recognized graduate school of medicine, or as resident in surgery in an acceptable hospital, or under a sponsorship accredited by the American Board of Surgery for such training.* By the latter statement is meant that one may secure the necessary training as an assistant to an accredited surgeon, provided suitable facilities for the education of the candidate are offered. It is understood that the board will accept a combination of training as outlined above.

(For example, one may take a graduate course in an acceptable graduate school for one year, a residency of two years, and an assistantship of two years.)

This period of special training shall be of such character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized. Knowledge of these sciences as applied to clinical surgery will be required in the examination.

Adequate operative experience in which the candidate has assumed the whole responsibility will be required.

The above requirements, especially those referring to surgical training, are subject to change from time to time as the existing opportunities for training in this field of specialization may be broadened.

EXAMINATIONS

The qualifying examination will be divided into Part I (written) and Part II (clinical, bedside and laboratory). In both of these parts a knowledge of the practical application of the sciences fundamental to surgery will be required as previously stated.

PART I

This may be given simultaneously in as many centers as the board may determine suitable for the purpose. A candidate, to be eligible for Part I, must meet all requirements for Group B candidates. A card of admission to this part of the examination will be forwarded to the candidate from the secretary's office, certifying that these requirements have been met, as well as due notice as to the time and place of examination.

The examination in Part I shall cover a one day period. There shall be two sessions of three hours each. This written examination shall concern itself primarily with general surgical problems and in addition the application of the basic sciences of surgery to these problems.

PART II

In order to be eligible for Part II a candidate must have successfully passed Part I, in addition to having met the necessary preliminary requirements and having presented definite evidence of an adequate training in operative surgery satisfactory to the board.

This part of the examination shall be oral and practical and cover a one-day period, the schedule being arranged somewhat as follows:

8-9 A. M.—REGISTRATION

9 A. M.—12 Noon.—Clinical Surgery (diagnosis and management and the application of physiology, biochemistry and bacteriology, as the case being examined on may offer an opportunity for doing so. X-ray plate interpretation will also be included).

2-5 P. M.—Applied anatomy and surgical pathology.

It is probable that for the present this part of the examination can be held in one center or at the most, two. Later, however, as the demand grows, it will be necessary, in all probability, for the board to establish definite subsidiary board centers where this part may be held. At that time it will be necessary that the board appoint subsidiary boards in these centers, consisting of those already qualified as in Group A, to conduct this examination.

* The board makes no attempt to classify hospital residencies, usually accepting those approved by the American College of Surgeons and the Council on Medical Education and Hospitals of the American Medical Association.

GRADES

A candidate must receive a passing average for each part to be entitled to the board's certificate. No candidate shall pass a part who does not receive a grade of 60% or over in each subject of such a part. An average grade of 75% shall be considered as passing in each part. The following values have been assigned to Part II on the basis of the total of 100%; clinical surgery 50%, anatomy 30%, pathology 20%.

A candidate who fails in his examination in Part I shall have his papers reviewed by the examination committee.

REEXAMINATIONS

Candidates may be reexamined as often as they desire provided one year shall elapse between examinations, except that the board may, for good and sufficient reason, deny a candidate the privilege of reexamination.

Candidates shall be required to pay the same fees for Parts I and II at each reexamination in these parts.

FEES

The fee for Group A, Founders Group, shall be \$25.

The fee for Group B shall be \$75, payable as follows: \$5 registration fee, which shall be returned if the candidate is not accepted for examination; \$20 for Part I; and \$50 for Part II.

This board is a non-profit organization. All fees will be used, after a reasonable amount is set aside for necessary expenses in maintaining its office, conducting examinations, etc., to aid in improving existing opportunities for the training of the surgeon.

CERTIFICATE

A certificate attesting to a candidate's qualification in surgery after meeting the requirements will be issued by the board, having been signed by its officers.

REVOCATION OF CERTIFICATE

Any certificate issued by the board shall be subject to revocation by the board at any time in case it shall determine in its sole judgment that a candidate, who has received a certificate, either was not properly qualified to receive it or has become disqualified since its receipt.

Proper forms for making application, and other information, will be furnished by the secretary-treasurer.

AMERICAN BOARD OF UROLOGY, Inc.

HERMAN L. KRETSCHEMER, President, Chicago.

CLARENCE G. BANDLER, Vice President, New York.

GILBERT J. THOMAS, Secretary-Treasurer, 1009 Nicollet Avenue, Minneapolis.

NATHANIEL P. RATHBUN, Brooklyn.

GEORGE GILBERT SMITH, Boston.

CHARLES C. HIGGINS, Cleveland.

HENRY G. BUGBEE, New York.

ALFRED I. FOLSOM, Dallas, Texas.

T. LEON HOWARD, Denver.

ORGANIZATION

At the annual meeting of the American Association of Genito-Urinary Surgeons held at Niagara Falls, Ont., Canada, May 26-28, 1932, Dr. William F. Braasch called attention to the various qualification boards which had been established, or were in the process of being established, for the certification of specialists. He suggested that a committee should be appointed from this organization to investigate the advisability of establishing a similar board for the specialty of urology. A committee consisting of Dr. Braasch as Chairman, Dr. Henry G. Bugbee, and Dr. Hugh H. Young was appointed. This committee reported to the society in 1933, was reappointed to continue its efforts, and was given the power to act.

At the meeting of the American Urological Association in 1933, Dr. George R. Livermore, in his presidential address, suggested that all candidates for specialization in urology should have some definite preparation, and should be required to take a thorough examination before being recognized as specialists in urology. Dr. Livermore appointed Dr. Joseph F. McCarthy, chairman; Dr. George Gilbert Smith, and Dr. Herman L. Kretschmer as a committee to study this suggestion.

At the annual meeting of the American Medical Association in Milwaukee, June 12-16, 1933, a committee consisting of Dr.

Montague L. Boyd, chairman; Dr. A. I. Folsom and Dr. Frank Hinman was appointed to cooperate with similar committees from the American Association of Genito-Urinary Surgeons and the American Urological Association in the establishment of the American Board of Urology.

The first combined meeting of the committees from these three organizations was held on Oct. 11, 1933, in Chicago. Dr. Herman L. Kretschmer was made president; Dr. Joseph F. McCarthy, vice president; and Dr. William F. Braasch, secretary. These men were elected to serve as temporary officers. A permanent organization could not be effected, however, because the committee from the American Urological Association had not been given the power to act.

The second meeting of these committees was held in New York City, Feb. 2, 1934. Dr. Nathaniel P. Rathbun, president of the American Urological Association, was present at this meeting.

At the annual meeting of the American Urological Association held in Atlantic City, N. J., May 22-24, 1934, the committee reported the activities of the temporary "Board of Urology." This report, which contained suggestions for the guidance of future committees from this association, was accepted, and a new committee was elected by the association, and was given the power to act.

The permanent "American Board of Urology, Inc.," was organized at Chicago, Sept. 24, 1934. The committee members present from the American Association of Genito-Urinary Surgeons were: Dr. William F. Braasch, Dr. Henry G. Bugbee, and Dr. Gilbert J. Thomas; those from the American Urological Association were: Dr. Nathaniel P. Rathbun, Dr. Herman L. Kretschmer, and Dr. George Gilbert Smith; those from the Section on Urology of the American Medical Association were: Dr. A. I. Folsom, Dr. T. Leon Howard, and Dr. Clarence G. Bandler.

The officers of the board elected at this meeting were: Dr. Herman L. Kretschmer, president; Dr. Clarence G. Bandler, vice president; Dr. Gilbert J. Thomas, secretary-treasurer.

The board was incorporated May 6, 1935, and held its first legal meeting May 10, 1935.

PURPOSES

The first objective of the American Board of Urology, Inc., is to render better service to the public by insuring the competence of any physician or surgeon who is specializing, or who wishes to specialize, in the field of urology. It will elevate the standards and advance the cause of urology. It will investigate the curricula of medical schools, and will encourage adequate facilities for graduate instruction in urology.

FUNCTIONS

(a) The board will arrange to control and conduct examinations testing the qualifications of volunteer candidates.

(b) The board will grant and issue certificates or other evidence of special knowledge in the field of urology to voluntary applicants or to candidates for certification.

(c) The board will endeavor to serve the public, hospitals, medical schools, medical societies and practitioners of medicine and surgery by preparing lists of urologists whom it has certified.

LIMITATIONS OF FUNCTIONS

The conferring of degrees, "Doctor of Medicine" or "Bachelor of Medicine" remains with the universities, where it belongs, and this board makes no attempt to control the practice of urology by license, or legal regulations. This board does not intend in any way to interfere with or limit the professional activities of any duly licensed physician.

REASON FOR APPLYING FOR A CERTIFICATE; ITS VALUE

The American Urological Association, the American Association of Genito-Urinary Surgeons, and the Section on Urology of the American Medical Association are interested in furthering the cause of urology and have participated in the formation of this board. They are sponsoring its activities. The various national medical societies, the public, hospital directors and others, will utilize the certification from this board as a means of discriminating between those well grounded as specialists in urology, and those who are not.

Lists of individuals who have certificates from this board, and who are engaged in the practice of urology may be published in the Directory of the American Medical Association and will be published in a booklet issued from time to time by the American Board of Urology, Inc. The directory of the American Medical Association may indicate, by symbols in the

biographical data, those whose names are eligible to appear on the list of diplomates of this board.

Application for this certificate is purely voluntary. There is only one type of certificate. No indication is given as to whether or not the candidate received his certificate with or without examination. All certificates are identical.

The Advisory Board for Medical Specialties working in conjunction with, and reporting to, the Council on Medical Education and Hospitals of the American Medical Association, has set certain standards of preparation for specialization which the American Board of Urology, Inc., wishes to adopt. The advisory board has drawn from the experience of all the present functioning boards, and has been of inestimable assistance in the formulation of the Constitution and By-Laws for the Board of Urology. Other organizations which now successfully operate boards of certification are:

The American Board of Ophthalmology, the American Board of Otolaryngology, the American Board of Obstetrics and Gynecology, the American Board of Dermatology and Syphilology, the American Board of Pediatrics, the American Board of Psychiatry and Neurology, the American Board of Radiology, the American Board of Orthopedic Surgery, the American Board of Internal Medicine, the American Board of Pathology and the American Board of Surgery. Among the organizations cooperating with the Advisory Board for Medical Specialties are: the Association of American Medical Colleges, the American Hospital Association, the Federation of State Medical Boards of the U. S. A., and the National Board of Medical Examiners.

APPLICATION BLANK: REQUIREMENTS FOR ALL APPLICANTS

Application for certification must be made on a special blank. This will be provided by the secretary and must be returned to him accompanied by other required data and credentials, and by \$15 of the examination fee.

Requirements for Applicants. (Article VIII, Section 2, of the By-Laws of the American Board of Urology, Inc.)

Each applicant, before he shall become eligible to take the examination for certification in urology, must:

A. Have graduated from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, and must have completed an internship of not less than one year in a hospital approved by the same council. (The former requirement is not applicable to a candidate who graduated from an institution now extinct, or whose graduation occurred before the American Medical Association had prepared a list of accredited medical schools.) All graduates of foreign medical schools must obtain a license in the state in which they propose to practice medicine and the certificate of the National Board of Medical Examiners before making application for certification.

B. Establish in a manner satisfactory to this board that he is a physician duly licensed by law to practice medicine, that he is of high ethical and professional standing and that he has received adequate special training in urology.

The board is attempting to increase and to standardize the facilities for urological training in teaching institutions, so that the expression "special training in Urology" may be interpreted to include:

1. A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in the special field of Urology.

This period of specialized preparation should include:

(a) graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty of Urology.

(b) an active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the diagnosis and treatment of urologic conditions.

(c) examinations in the medical sciences basic to the specialty of Urology, as well as in the clinical, laboratory and public health aspects.

2. An additional period of not less than two years in the private practice of urology in the city from which he makes application.

These special requirements conform with the suggestions made by the Council on Medical Education and Hospitals of the American Medical Association.

C. Make application to the American Board of Urology, Inc., whose duty it shall be to investigate the applicant's credentials and make a survey of his character;

D. Assure the board that he is engaged in the practice of urology and that he intends to continue to be so engaged;

E. Membership in the American Medical Association, or comparable national medical society is recommended.

FEE

The examination fee will be \$75. Fifteen dollars must accompany the application. Sixty dollars is to be paid when the applicant is accepted as a candidate for certification. This is the total expense to the candidate. If a candidate fails in his examination, he will be permitted a second examination after one year, or within three years, without additional fee, but he must give sixty days' notice of his intention to appear for reexamination. After an applicant has failed twice, he must file a new application blank accompanied by a second fee. If an applicant is lacking in any of the requirements as stated above, he will be considered ineligible for examination and classification and his fee will be returned. In no other instance, however, will a refund of the examination fee be possible.

REQUIREMENTS FOR CERTIFICATION

According to the By-laws of the American Board of Urology, Inc., applications received from applicants for certification shall be examined by the Credentials Committee and reviewed by the board. When additional data are required to complete the application, these will be requested by the secretary's office.

The requirements for certification include: personal appearance before the board; preparation of fifty case reports of major urological cases under the candidate's own supervision which must contain all items essential for diagnosis, therapy, prognosis, results of treatment, etc.; oral and clinical examinations; written examinations.

In specific instances, the board may waive any part of these requirements, with the exception of the item of personal appearance.

Each candidate will receive a notice of the time and place of the examinations, and an appointment for his personal appearance before the board.

EXAMINATIONS, WHERE HELD, AND REPORTS OF CASE HISTORIES

The board will hold one examination a year. This will be held at a time or place that the board may select or deem expedient.

1. The *written examinations* are designed to test the candidate's preparation in, and his knowledge of, the whole subject of urology, including the fundamental subjects: pathology, anatomy, physiology, embryology, bacteriology, physiological chemistry and endocrinology. The examination in pathology will consist of the identification of gross specimens and of sections of tissue observed through the microscope. The examination in anatomy, physiology, embryology, bacteriology, physiological chemistry, and endocrinology will be a test of the candidate's working knowledge of these subjects as they are related to the practice of urology.

2. The oral and clinical examinations will consist of discussions of common urologic conditions. The subjects forming the basis of the oral examinations are urography, diseases of the genital organs, including the prostate, diseases of the urinary bladder, and diseases of the ureters and kidneys. The oral examination may deal directly with the reports of case histories which the candidate has submitted. This examination will ascertain the candidate's familiarity with recent urologic literature, the breadth of his clinical experience, and his general qualifications as a specialist in urology. The applicant also will be examined in "professional adaptability" in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

3. The *reports of fifty major urological cases* must be consecutive and must have been under the candidate's own supervision. They must not be abstracted. Sufficient data should appear in these so the examiner will know that a proper history was taken and that a thorough examination, including a complete physical survey, was made.

Case reports that are copied verbatim from a hospital record are not desired. They must be identified by the name of the hospital and the case admission numbers, with the pertinent dates. The reports must be typewritten (preferably on 8½ by 11 paper) and in duplicate, but need not be on any special forms.

The data should be placed under proper headings and the arrangement of these should conform to the sequence of events incidental to the patient's admission to the hospital or clinic, the examinations made and treatment prescribed.

Each candidate must assume personal responsibility for the data in his case reports, including autopsy findings and interpretations of urograms. If the reports are prepared by record clerks, interns, or fellows, they should be reviewed by the candidate and careful attention given to the spelling and the correct use of medical terms before submitting them to the secretary of the board. Case reports are documentary evidence of a can-

didate's method of practice, and the data in them and the manner in which these are presented reflect this.

Satisfactory case reports must be submitted before a candidate will be permitted to continue with other parts of his examination. If case reports are pronounced unsatisfactory by more than one examiner, the candidate will be informed of this and requested to prepare others. Criticisms and unsatisfactory reports will be sent to the candidate upon request.

Case reports must be submitted to the secretary of the board at least ninety days before the time set for the oral-clinical examination.

Although the board requires that all the essential points of the history and examination be given, as well as a complete description of the surgical procedure, emphasis should be placed on the following items: preoperative diagnosis; clinical and pathological diagnosis; summary of postoperative course with special reference to morbidity; clinical findings at time of discharge from the hospital and subsequent "follow-up" reports.

A final short paragraph must be prepared for each case by the candidate. These data must include the candidate's interpretation of the history in terms of pathology; the basis for the diagnosis; the facts that determined the treatment prescribed, whether surgical or otherwise; the course of treatment to be pursued following discharge from the hospital or clinic; a critical discussion of the knowledge gained from the proper handling of the case, or from the errors made (if any) in the diagnosis and method of treatment.

Complete separate index lists of the case history reports submitted must accompany the records. If the reports are obtained from more than one hospital they must be consecutive, as mentioned before, and a separate complete index list of each group of reports should be provided. These lists must state the operator's name at the head of each page, the name of the patient, the hospital and admission number, and the date of operation. The lists will be filed in the secretary's office for verification purposes.

Case reports will be reviewed by examiners living in localities other than those where the candidates practice.

FINAL ACTION

Final action is based on the applicant's training, his professional record, his attainments in the field of urology, and the results of the examinations. Any well trained urologist will have no difficulty in obtaining the board's certification. This board is organized not to prevent qualified urologists from obtaining certificates, but to assist them in becoming recognized in their communities as men competent to practice in the special field of urology.

The activities described in Articles IX and X of this pamphlet proceed from the certificate of incorporation in which is stated the nature of the business, objects, and purposes proposed to be transacted and carried out by this corporation.

REVOCATION OF CERTIFICATE

Certificates issued by this board are subject to the provisions of the Articles of Incorporation and the By-laws. According to Article IX, Section 4, of the By-laws, "each certificate may be revoked in the event that:

(a) The issuance of such certificate or its receipt by the physician so certified shall have been contrary to, or in violation of, any provision of the Certificate of Incorporation of this, the American Board of Urology, Inc., or of the By-laws; or

(b) The physician or party certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to, or could have been ascertained by, the directors of the board at the time of the issuance of such certificate; or

(c) The physician or party so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the board or its representatives; or

(d) The physician so certified, at any time while continuing to practice, shall cease to practice urology; or

(e) The physician so certified shall at any time have neglected to maintain the degree of competency in the practice of the specialty of urology as set up by the board, and shall refuse to submit to reexamination by the board.

The Board of Trustees of this Corporation shall have the sole power, jurisdiction and right, to determine and decide whether or not the evidence or information before it is sufficient to constitute one of the grounds for revocation of any certificate issued by this corporation, and the decision of such Board of Trustees in the premises shall be final."

Communications should be addressed to the secretary-treasurer.

THE AMERICAN BOARD OF PLASTIC SURGERY, INC.

A SUBSIDIARY OF THE AMERICAN BOARD OF SURGERY

JOHN STAIGE DAVIS, Chairman, Baltimore.
GEORGE M. DORRANCE, Vice-Chairman, Philadelphia.
VILRAY P. BLAIR, Secretary-Treasurer, 400 Metropolitan Building, St. Louis.
CONRAD BERENS, New York.
JAMES BARRETT BROWN, St. Louis.
ROBERT H. IVY, Philadelphia.
HAROLD L. D. KIRKHAM, Houston, Texas.
WILLIAM S. KISKADDEN, Los Angeles.
SUMNER L. KOCH, Chicago.
WILLIAM E. LADD, Boston.
GORDON B. NEW, Rochester, Minn.
GEORGE WARREN PIERCE, San Francisco.
ERNEST FULTON RISON, Toronto, Ontario.
FERRIS SMITH, Grand Rapids, Mich.
JEROME P. WEBSTER, New York.

HISTORY

The aim of the American Board of Plastic Surgery is much the same as that outlined by the American Board of Surgery, namely, "to support a movement which it believes will ultimately raise the standards of qualified surgeons in this country and aid in improving opportunities for the training of the surgeon." A specific purpose of the board is to certify those plastic surgeons found to be qualified, after meeting reasonable requirements, for the protection of the public and the good of the specialty.

PURPOSES

The purposes of the board are:

1. To elevate and establish standards of fitness to practice plastic surgery.
2. To arrange and conduct examinations to test the qualifications of those who practice plastic surgery and to confer certificates upon those who meet the standards established by the board.
3. To improve and widen the existing opportunities for the training of the plastic surgeon.
4. To study and evaluate local and foreign teaching centers and opportunities for experience in and the study of plastic surgery.

REQUIREMENTS

1. Moral and ethical standing in the profession satisfactory to the board.
2. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies shall not be required.
3. Those who are adequately trained for and are doing acceptable work in the practice of plastic surgery in any field.
4. In exceptional instances the board may, in its discretion, accept for examination candidates who have met all preliminary requirements and have been in practice from six to sixteen years but whose formal training does not comply with the full requirements to be exacted in the future.

The board recognizes two groups of candidates who may be eligible for certification.

(A) The Founders Group—those who have already amply demonstrated their fitness as trained specialists in plastic surgery. Candidates from this group on invitation by the board, and those who voluntarily request, may make application, and on approval by the board and by the American Board of Surgery will be accepted without examination as qualified.

(B) Those qualified by examination.

PROFESSIONAL STANDING

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association or graduation from an approved foreign school.
2. Completion of an internship of not less than one year in a hospital approved by the said Council, or its equivalent, in the opinion of the board.
3. For all candidates applying for certification by this board in one or more special fields, preliminary certification from the certifying board or boards of these individual specialties shall be considered essential. For all candidates applying for certification in the general field of plastic surgery, preliminary certification by the American Board of Surgery will be essential, except as noted in paragraph (4) under Requirements.

SPECIAL TRAINING

For certification in the general field of plastic surgery, the following special training shall be required: A period of graduate study in surgery of not less than five years beyond the intern year, two years of which shall be devoted to plastic surgery, to be taken in a recognized graduate school or hospital, or under a sponsorship accredited by both the American Board of Surgery and the American Board of Plastic Surgery. This period of special training shall cover the technical and clinical phases of plastic surgery and the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry as they are related to plastic surgery. For candidates seeking certification in the general field of plastic surgery, this latter basic part of the preparatory work shall be approved by the American Board of Surgery before the candidate is eligible for examination by the American Board of Plastic Surgery.

For candidates for certification in special fields, preliminary certification by the related special board shall be accepted as evidence of basic training in that specialty, but shall not be accepted as evidence of adequate training in the conduct of anesthesia, control of hemorrhage, treatment of shock, in bacteriology, and in the care of surgical infection and accidents.

EXAMINATIONS

The qualifying examination will be divided into Part I, written, and Part II, oral and practical.

Nature of Examinations.—For the general plastic group, Part I shall consist of a written examination given by the American Board of Surgery. The examination of candidates in special fields without preliminary certification by the American Board of Surgery shall include questions upon the management of local and general anesthesia, shock, hemorrhage, surgical pathology, the handling of tissues and related bacteriology, surgical complications, etc., this examination to be given by the American Board of Plastic Surgery.

Part II as it applies to the general plastic field shall be that as conducted by the American Board of Surgery, it being understood that the clinical part of the examination shall be conducted by examiners appointed by the American Board of Plastic Surgery.

The clinical examination by the American Board of Plastic Surgery shall include any or all of the following:

- (a) The exhibition of patients who have undergone or are undergoing treatment.
- (b) Examination, diagnosis and presentation of a plan of correction by the applicant of cases provided by the examiners.
- (c) Oral examination of the applicant and observations made in the operating room, treatment rooms and wards.

In order to be eligible for Part II of the examination, a candidate must have successfully passed Part I.

GRADES

A candidate shall be required to receive a passing average for each part in order to receive the board's certificate. No candidate shall pass Part I or Part II of the examination who does not receive a grade of 60 per cent or over in each subject of such a part. An average grade of 75 per cent shall be considered as passing.

REEXAMINATIONS

Candidates may be reexamined as often as they desire, provided that one year shall elapse between examinations, except in such cases as the board may, for good and sufficient reason, deny a candidate the privilege of reexamination. Candidates shall be required to pay the fee for either Part I or Part II previous to each reexamination in these parts.

FEES

The fee for Group A (Founders' Group) shall be \$25.

The fee for Group B shall be \$75, payable as follows: \$25 on registration; \$25 for Part I of the examination, of which \$10 shall go to the American Board of Surgery; \$25 for Part II of the examination.

There shall be no refunds.

CERTIFICATE

A certificate attesting to a candidate's qualifications in plastic surgery after meeting the requirements will be issued by the board, having been signed by its officers.

REVOCATION OF CERTIFICATE

Any certificate issued by the board shall be subject to revocation by the board at any time in case it shall determine in its sole judgment that a candidate who has received a certificate either was not properly qualified to receive it or has become disqualified since its receipt.

Proper forms for making application and other information will be furnished by the secretary-treasurer.

 ERNEST SACHS, St. Louis, Mo.
 BYRON STOOKEY, New York.

ORGANIZATION

Recognizing the need for detailed training and special qualifications for the practice of neurological surgery, representatives of both the Society of Neurological Surgeons and the Harvey Cushing Society held an informal meeting in Chicago on March 27, 1939, to consider the advisability of the formation of a national certification board. Later the group was enlarged by representatives from the Section on Nervous and Mental Diseases of the American Medical Association, the Section on Surgery of the American Medical Association, the American Neurological Association, and the American College of Surgeons. Approval of the board by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association was given. The American Board of Neurological Surgery was incorporated in the State of Delaware on Aug. 1, 1940.

The membership of the corporation was nominated as follows: five from the Society of Neurological Surgeons, three from the Harvey Cushing Society, one each from the American College of Surgeons, the Section on Nervous and Mental Disease of the American Medical Association, the Section on Surgery of the American Medical Association, and the American Neurological Association.

PURPOSES

A. To encourage the study, improve the practice, elevate the standards and advance the science of neurological surgery and thereby to serve the cause of public health.

B. To grant and issue to physicians duly licensed by law, certificates or other recognition of special knowledge in neurological surgery and to suspend and revoke the same.

C. Certificates granted or issued by the corporation shall not confer or purport to confer on any person any legal qualification, privilege or license to practice neurological surgery, nor purport to be issued under or in pursuance to or by virtue of any statutory or governmental sanction or authority.

D. To determine by examination, investigation and otherwise the fitness and competence of specialists in neurological surgery who shall apply for certificates and to prepare, provide, control and conduct examinations, written, oral and otherwise, for such purpose and to determine the results of such examination.

E. To furnish to the public, hospitals, medical schools, medical societies and practitioners of medicine and surgery lists of neurological surgeons who from time to time have been granted certificates by this corporation.

GENERAL REQUIREMENTS

A. General qualifications.

1. Satisfactory moral and ethical standing in the profession.

2. License to practice medicine.

3. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

4. That the surgical activity of the applicant shall be limited to neurological surgery.

B. Professional education.

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school which is acceptable to the American Board of Neurological Surgery, Inc.

C. Special training, to be effective Jan. 1, 1940.

1. Completion of a surgical internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, or its equivalent in the opinion of the board.

2. A period of graduate study in a recognized graduate school of medicine of not less than three years beyond the intern year, or in an approved hospital or under a sponsorship acceptable to the American Board of Neurological Surgery, Inc., for the training of neurological surgeons. This period of special training shall be of such a character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized. Knowledge of these sciences as applied to the practice of neurological surgery will be required in the examination.

3. An additional period of not less than two years in the practice of neurological surgery.

D. Certification without examination.

1. On invitation by the board and written application made within two years from Jan. 1, 1940, the following may be accepted as eligible for certification upon approval of the board of directors and on the production of evidence of satisfactory moral and ethical standing in the profession.

(a) Individuals of professorial rank in approved medical schools of the United States or Canada whose surgical practice is limited to neurological surgery.

(b) Those who have specialized in neurological surgery for ten years prior to Jan. 1, 1940.

APPLICATION BLANK AND FEE

Application must be made on the special form which may be procured from the secretary. The application and examination fee for candidates is \$75 whether certified with or without examination. The completed application form should be returned to the secretary accompanied by an application fee of \$25. When notified by the secretary that he is eligible for examination he shall send the examination fee of \$50 to the secretary-treasurer at least two weeks before the date of examination. The application fee will be returned if the candidate is not accepted by the board for examination.

A candidate who has failed in one examination is eligible to reexamination in the subject, or subjects, in which he failed, within three years, on payment of a reexamination fee of \$10. A candidate who has failed in one examination and who does not apply for reexamination within three years or a person who has applied within that time but who has failed a second time will be considered a new applicant.

EXAMINATIONS

Examinations will be held in the spring and fall of each year at or near the time and place of a national meeting at the discretion of the board. Examinations will be oral and based upon broad principles of neurological surgery. The subject matter of the examination will be divided into six parts: (1) neuroanatomy and neurophysiology, (2) neuropathology and bacteriology, (3) ophthalmology and x-ray diagnosis, (4) neurosurgical problems, (5) organic neurology and (6) general surgery.

The first examination will be held at the Neurological Institute, University of Illinois, 912 South Wood Street, Chicago, on Oct. 18 and 19, 1940.

All communications should be addressed to the secretary-treasurer.

ADVISORY BOARD FOR MEDICAL SPECIALTIES

Organized 1933-1934 to coordinate graduate education and certification of medical specialists in the United States and Canada.

This Board reports directly to its member groups, and functions in close cooperation with the Council on Medical Education and Hospitals of the American Medical Association and with the Advisory Council on Medical Education.

The work of this Board has been aided by grants from the Josiah Macy Jr. Foundation of New York, but the Board is now supported by its component groups.

OFFICERS AND EXECUTIVE COMMITTEE

WILLARD C. RAFFLEYE, President, New York.

WILLIAM P. WHERRY, Vice President, Omaha.

MEMBER EMERITUS

LOUIS B. WILSON, Rochester, Minn.

The Advisory Board for Medical Specialties has prepared this booklet for the purpose of furnishing general information regarding its activities in connection with graduate medical education and the certification of medical specialists in the United States and Canada. It is designed also to give detailed information concerning the procedure to be followed by examining boards in the various specialties in order to obtain membership in this Advisory Board and official recognition by the Council on Medical Education and Hospitals of the American Medical Association. This information is based in large part on the experience of previously formed boards during the past twenty-three years.

Examining boards have now been organized, approved, and are actively functioning in the thirteen specialties recognized as suitable fields for the certification of specialists. Two of the

more limited specialties, namely, anesthesiology and plastic surgery have examining boards as affiliates of the American Board of Surgery.

The Committee on Standards and Examinations of the Advisory Board and the Council on Medical Education and Hospitals of the American Medical Association express themselves as opposed to the organization of examining boards in any special field having less than one hundred in the United States engaged in the special practice in question.

ORGANIZATION

Several American Boards had been functioning actively and successfully for a number of years prior to the organization of the Advisory Board for Medical Specialties. Their purposes were, primarily, to establish minimum standards of graduate educational and training requirements for physicians representing themselves to the public as being specialists, with certification by the boards of candidates after they had been able successfully to pass the boards' examinations. Secondly, these boards hoped to improve the general standards of graduate medical education and facilities for special training. This aim is being steadily and rapidly accomplished.

Credit for the improvement in undergraduate medical education, so noticeable in this country during the past twenty-five years, is due to the efforts of universities, educational foundations, medical schools, medical societies, and to public support along these lines. The same is true of the present transition in graduate education in the specialties, sharply stimulated by the establishment and activities of these certifying boards.

The American Board of Ophthalmology was the first special certifying board to be created in 1916; the American Board of Otolaryngology, established in 1924, was followed by the American Board of Obstetrics and Gynecology in 1930, and the American Board of Dermatology and Syphilology in 1932.

During part of this period of time plans for the organization of similar boards in other specialties were being actively projected, all of these groups being desirous of availing themselves of the experiences of the already existing boards.

It was soon recognized that some formal and official plan of organization must be established. It was clearly essential that an examining board must have the official sanction of the national societies in its given specialty as well as that of its section of the American Medical Association, but there was, at that time, nothing to prevent unofficial groups from organizing examining boards and using the title American Board.

Consequently, in order to avoid duplication of effort as well as to coordinate the work of the several boards and other interested groups into a concise and homogeneous plan for betterment, it was deemed advisable to create an Advisory Board which should give consideration to those problems common to all, and which should be representative of each organization concerned.

During the years 1933 and 1934 this Advisory Board was organized and began actively to function. Simultaneously at the Milwaukee session of the American Medical Association in 1933 a resolution was adopted authorizing the Council on Medical Education and Hospitals: (1) to formulate standards of administration based in general upon those of the American Boards of Ophthalmology, of Otolaryngology, of Obstetrics and Gynecology, and of Dermatology and Syphilology and, (2) to recognize officially new boards meeting these standards, this recognition to be based upon previous approval and recommendation to the Council by the Advisory Board.

A constitution and by-laws for the Advisory Board was adopted at a meeting in Chicago on February 11, 1934. The original member organizations of the Advisory Board for Medical Specialties were: the Association of American Medical Colleges; the American Hospital Association; the Federation of State Medical Boards of the U. S. A.; the National Board of Medical Examiners; the American Board of Ophthalmology; the American Board of Otolaryngology; the American Board of Obstetrics and Gynecology, and the American Board of Dermatology and Syphilology. Two representatives were appointed from each of these organizations to serve on the Advisory Board. Since that time the American Boards of Pediatrics, of Psychiatry and Neurology, of Radiology, of Orthopaedic Surgery, of Urology, of Pathology, of Internal Medicine, of Surgery, and of Neurological Surgery have been properly organized, approved, and elected to membership in the Advisory Board and recommended to the Council on Medical Education and Hospitals of the American Medical Association for official recognition. The American Board of Surgery now has two affiliate Boards (Anesthesiology and Plastic Surgery) functioning under its general direction and also represented in the Advisory Board.

PURPOSE

Article II of the Constitution states that, "This board shall act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists." Specifically, this represents an official effort to advance the standards and improve the methods of graduate education and training in the medical specialties, with certification of men thus educated and trained who qualify as specialists in the various branches. The common interest of the member organizations in these purposes is obvious. It is equally apparent that some fixed definition of specialties needed to be established, preferably on a graduate educational basis, that minimum standards of organization and conduct for new examining boards should be fixed, and that some official method of recognition be developed.

There is no desire on the part of these boards to interfere with any practitioners of medicine in any of their regular or legitimate activities. Their fundamental purpose is to ensure to the public, both lay and medical, and for its protection, that physicians claiming to be specialists with presumably special proficiency in one or another branch of medicine actually possess the qualifications they claim. This presupposes special training and demonstrable capability along certain lines of work. Suitable evidence of this is the ability of an individual to satisfy an examining board about his training and then to pass the examination for certification.

The function of each member organization and the relationship of interests will be apparent from a review of the names of these committees and boards.

Preparations for providing medical school and hospital facilities for the required graduate training are going forward actively; surveys of existing facilities for assistant residencies and residencies are being made at the present time in the several specialties; previous activities in the various States respecting the issuance of licenses to specialists are being discussed with a view to their being coordinated with the present activities of the several specialty boards. Several of the American boards, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association, are conducting surveys of institutions providing acceptable residencies and internships.

A Directory of Medical Specialists to include the names and biographic data of all men certified by the several specialty boards, as well as information regarding the organization and functions was published early in 1940. The first edition of the Directory contained the names and brief biographic records, including hospital and teaching appointments of more than 14,000 diplomates or certified specialists, and completely revised editions are to be issued every two years.

The Council on Medical Education and Hospitals of the American Medical Association has agreed, under the authority vested in it by the resolution passed at the Milwaukee meeting (1933) and referred to above, that applications of special examining boards for official approval are to be referred to the Council through the Advisory Board for Medical Specialties, recommendation by the Advisory Board for such approval to be based upon the standards mutually adopted. The understanding exists that the Council cannot be bound by recommendations of the Advisory Board but will consult the Advisory Board for Medical Specialties before acting upon any application so long as mutually adopted standards are in force.

In response to the generally recognized need for a clear formulation of the educational problems and principles involved in graduate and postgraduate medical training, the Advisory Board at its meeting in June 1937 voted to create a Commission on Graduate Medical Education to study the various aspects of the whole problem. This commission includes representatives of the profession, the specialties, the universities, the hospitals, and the licensing bodies. The results of the study contemplated should be of real assistance to the various specialty boards, hospitals, medical schools, and regulatory bodies dealing with this phase of American medicine.

MEMBERSHIP

The Advisory Board is composed of two representatives from each of the approved examining boards in the medical specialties and such other national organizations as are interested in education, examination, and certification of medical specialists and duly elected to this body.

The Constitution provides that, "To be eligible for representation in this board an examining board in a specialty must be composed of members elected from or appointed by societies recognized by this board as a national society in that specialty together with representation from the related section of the

American Medical Association." Upon being accepted by the Advisory Board the Board in question is recommended to the Council on Medical Education and Hospitals of the American Medical Association as qualified for recognition. Membership in the Advisory Board provides for the inclusion of the name of the organization in all lists and directories published by the Advisory Board for Medical Specialties and provides also for publication of the names of specialists certified by each individual examining board.

Meetings of the Advisory Board for Medical Specialties are held annually as required.

Traveling and other expenses of representatives in attendance are borne by member organizations.

ESSENTIALS FOR APPROVED SPECIAL EXAMINING BOARDS

(Adopted by the Advisory Board for Medical Specialties, June 10, 1934)

I. ORGANIZATION

1. A special examining board to be approved by the Advisory Board for Medical Specialties should represent a recognized and distinct specialty of medicine. (It is agreed between the Council and the Advisory Board that no board shall be organized in a special field having less than one hundred members engaged in special practice in the United States.)

2. It should be composed of representatives of the national organizations in that specialty including the related section of the American Medical Association.

3. It should be incorporated.

4. A special board should:

(a) Determine whether candidates have received adequate preparation.

(b) Provide a comprehensive test of the ability and fitness of such candidates.

(c) Certify to the competence of those physicians who have satisfied its requirements.

II. DEFINITION OF SPECIAL FIELDS

The following branches of medicine at present are recognized as suitable fields for the certification of specialists:

1. Internal Medicine
2. Surgery
3. Pediatrics
4. Obstetrics and Gynecology
5. Ophthalmology
6. Otolaryngology
7. Dermatology and Syphilology
8. Psychiatry and Neurology
9. Urology
10. Orthopaedic Surgery
11. Radiology
12. Pathology

III. QUALIFICATION OF CANDIDATES

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

A. General Qualifications.

1. Satisfactory moral and ethical standing in the profession.

2. Membership in the American Medical Association or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association is recommended. Membership in other societies should not be required. (Exceptions to the foregoing may now be made at the discretion of any individual board for good and sufficient reasons.)

B. Professional Standing.

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Completion of an internship, preferably of the general rotating type, of not less than one year in a hospital approved by the same Council.

C. Special Training.

(To be effective as far as practical not later than January 1, 1942.)

1. A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council as competent to provide a satisfactory training in the special field of study.

2. This period of specialized preparation should include:

(a) Graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the specialty in question.

(b) An active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council as competent in the specialty.

(c) Examinations in the basic medical sciences of a specialty as well as in the clinical, laboratory and public health aspects.

3. An additional period of not less than two years of study and/or practice.

The foregoing report is practically identical with an outline of Essentials for Approved Specialty Boards adopted June 10, 1934, by the Council on Medical Education and Hospitals of the American Medical Association and ratified June 11, 1934, by the House of Delegates of the American Medical Association.

ORGANIZATION OF EXAMINING BOARDS

The foregoing essentials for approved special examining boards and their affiliate boards were followed in the organization of the existing boards.

Official sponsorship of the national societies, and the related section of the American Medical Association, in a specialty organizing an examining board, has included the election or appointment of representatives from each of these national societies to serve on the board as examiners and directors.

Each board was or is incorporated. Each application for organization and approval included:

1. The name of the proposed board.
2. A statement of its method of organization, the sponsoring societies, its list of officers, and the names and addresses of the elected or appointed members of the board, including the societies which each represents.
3. A copy of the tentative constitution and by-laws.
4. A copy of its proposed articles of incorporation.
5. An outline of qualification requirements for applicants.
6. An outline of proposed methods of examination.
7. A copy of the application blank.
8. Any general information or statement of importance.
9. Approximate number of physicians practicing the specialty which the Board represents.

These data are submitted in duplicate to the office of the Secretary of the Advisory Board for Medical Specialties.

An application for election to membership in the Advisory Board and the data listed above are referred immediately for review by the Committee on Standards and Examinations of the Advisory Board. Upon approval by the Committee incorporation is then completed and a statement of this filed with the Secretary. Action on the application will be taken at the succeeding meeting of the Advisory Board for Medical Specialties and each examining Board as elected will be recommended to the Council on Medical Education and Hospitals of the American Medical Association for official recognition. One of the two sets of data submitted is forwarded to the Council on Medical Education and Hospitals of the American Medical Association with the Advisory Board's recommendations. Examination and certification of applicants in the specialty may begin immediately upon the special board being given such approval. Communications should be addressed to the secretary.

CONSTITUTION AND BY-LAWS

Adopted at Organization Meeting, February 11, 1934

ARTICLE I

NAME

The name of this organization shall be "The Advisory Board for Medical Specialties."

ARTICLE II

PURPOSE

This board shall act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists. No action taken by this Board shall be binding upon any member organizations.

ARTICLE III

MEMBERSHIP

Section I

This board shall be composed of two representatives from each of the examining boards of the medical specialties and such other national organizations as are interested in education, examination, or certification of medical specialists.

Section II—Original Membership

At the time of the organization, this board shall be composed of representatives from each of the following bodies:

- The American Board of Ophthalmology.
- The American Board of Otolaryngology

The American Board of Obstetrics and Gynecology
The American Board of Dermatology and Syphilology

The Association of American Medical Colleges

The National Board of Medical Examiners

The Federation of State Medical Boards of the U. S. A.

The American Hospital Association

The Council on Medical Education and Hospitals of the American Medical Association

Section III—Additional Membership

To be eligible for representation in this board an examining board in a specialty must be composed of members elected from or appointed by Societies recognized by this Board as National Societies in that specialty together with representation from the related Section of the American Medical Association. Upon being accepted by this Advisory Board the board in question will be recommended to the American Medical Association as being qualified for recognition by that Association.

Section IV—Quorum

A quorum at any meeting shall consist of a majority of the official representatives to the board and at least one-third of the membership organizations shall be represented. Each member organization shall be entitled to two votes.

ARTICLE IV

OFFICERS AND STANDING COMMITTEES

Section I—Officers

The officers of this board shall be (a) President, (b) Vice President, (c) Secretary-Treasurer. These officers shall be elected at the annual meeting each year.

Section II—Standing Committees

The standing committees shall be as follows:

1. The Executive Committee
2. Standards and Examinations
3. Finance

The Executive Committee shall consist of the President, Vice President, Secretary-Treasurer, and two members elected at the annual meetings. No organization should have more than one member on the Executive Committee. The President shall be the Chairman of the Executive Committee. The other standing committees shall be appointed by the President.

ARTICLE V

AMENDMENTS TO THE CONSTITUTION

Amendments to this constitution may be made by a majority vote of the official representatives present at any annual meeting provided that thirty days' notice of the proposed amendment has been given each member of the board.

BY-LAWS

ARTICLE I

DUTIES OF OFFICERS

Section I

The President shall preside at all meetings of the board, shall act as Chairman of the Executive Committee, and shall appoint all other standing committees. He shall call meetings of the Executive Committee at such time and place as may be deemed necessary.

Section II

The Vice President shall assume the duties of the President in his absence.

Section III

The Secretary-Treasurer shall perform the usual duties of this office.

ARTICLE II

EXECUTIVE COMMITTEE

The Executive Committee shall carry out the policies and activities decided upon by the board. It shall have an interim authority to initiate policies subject to approval by the board at the annual or any special meeting. The two elected members shall serve for two years, the terms of office terminating in alternate years.

ARTICLE III

MEETINGS

Section I

There shall be an annual meeting at such time and place as the board may determine. A special meeting may be called by the president upon ten days' notice to all members stating time, place and purpose of such meetings. The Executive Committee may present other business for consideration.

Section II

The Executive Committee shall meet subject to the call of the President.

Section III

Robert's Rules of Order shall be followed except where they conflict with this Constitution and By-Laws.

ARTICLE IV

AMENDMENTS TO THE BY-LAWS

Amendments to these by-laws may be made at any regular or special meeting of the board.

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

For the benefit of graduates of approved medical colleges who desire an internship in Canada, the Council on Medical Education and Hospitals of the American Medical Association has declared that hospitals which conform to the standards of the Department of Hospital Service of the Canadian Medical Association should be regarded as giving an internship equivalent in educational value to that offered by hospitals in the United States approved for intern training by the Council. It is understood, however, that this statement applies only to hospitals that are unqualifiedly "Approved" under the Canadian plan and does not apply to that group referred to as "Commended."

The following list of hospitals, revised to June 1, 1910, has been furnished by the Department of Hospital Service.

Name of Hospital	Location	Name of Hospital	Location	Name of Hospital	Location
Victoria General Hospital	Halifax, N. S.	McKellar General Hospital	Fort William, Ont.	Regina Grey Nuns' Hospital	Regina, Sask.
St. John General Hospital	St. John, N. B.	Hamilton General Hospital	Hamilton, Ont.	Regina General Hospital	Regina, Sask.
Hospital du St. Smerment	Quebec, Que.	St. Joseph's Hospital	Hamilton, Ont.	St. Paul's	Saskatoon
Hotel Dieu de Quebec	Quebec, Que.	Ottawa Civic Hospital	Ottawa, Ont.	Holy Cross	Edmonton
Hospital of the Infant Jesus	Quebec, Que.	Ottawa General Hospital	Ottawa, Ont.	Edmonton General Hospital	Edmonton, Alta.
Jeffrey Hale's Hospital	Quebec, Que.	Kingston General Hospital	Kingston, Ont.	Misericordia Hospital	Edmonton, Alta.
Children's Memorial Hosp.	Montreal, Que.	Hospital for Sick Children	Toronto, Ont.	Royal Alexandra Hospital	Edmonton, Alta.
"	Que.	Mount Sinai Hospital	Toronto, Ont.	University of Alberta Hosp.	Edmonton, Alta.
"	Que.	St. Joseph's Hospital	Toronto, Ont.	St. Paul's Hospital	Vancouver, B. C.
"	Que.	St. Michael's Hospital	Toronto, Ont.	Vancouver General Hospital	Vancouver, B. C.
"	Que.	Toronto East General Hosp.	Toronto, Ont.	Royal Jubilee Hospital	Victoria, B. C.
"	Que.	Toronto General Hospital	Toronto, Ont.	St. Joseph's Hospital	Victoria, B. C.
Jewish General Hospital	Montreal, Que.	Toronto Western Hospital	Toronto, Ont.		
Montreal General Hospital	Montreal, Que.	Women's College Hospital	Toronto, Ont.		
Royal Victoria Hospital	Montreal, Que.	Brantford General Hospital	Brantford, Ont.

Woman's General Hospital	(Westmount)	Victoria Hospital	London, Ont.		
		Metropolitan General Hospital	Windsor, Ont.		

NOTES

* Majority of patients available for teaching purposes.

† Internships available for one year beginning July 1, 1940; thereafter internships depend upon appropriations by Congress.

(a) In lieu of maintenance.

(b) Salary established by government pay tables.

(c) \$30 per month second year.

(d) Bonus of \$60.

1. Women interns admitted.

2. Women interns only.

3. Dental interns employed.

(e) Bonus of \$100.

(f) January, March, July, September, November.

(g) Bonus of \$120.

(h) Bonus of \$180.

(i) Bonus of \$10.

(j) Senior internships available.

(k) Bonus of \$25.

(n) Every two months.

(o) Bonus of \$50.

(p) Bonus of \$300.

(q) Bonus of \$150.

(r) Bonus of \$75.

(s) Bonus of \$24.

(t) Every six weeks.

(u) \$10 per month second year.

(w) \$25 per month first year; \$50 per month second year; bonus of \$100.

(x) Bonus of \$200.

(y) \$20 per month second year.

(z) Bonus of \$125.

(aa) Bonus of \$30.

(bb) February, June, July, October.

(cc) Bonus of \$250.

(dd) \$15 per month first year; \$30 per month second year; bonus of \$60 each year.

(ee) Bonus of \$240.

(ff) All internships reserved for the fifth year students of the College of Medicine, University of the Philippines.

Affiliation as Referred to in Column Headed: "Affiliated Service"

4. Patton State Hospital, Potton, psychiatry.
5. California Babies Hospital, Georgia Receiving Hospital, Los Angeles, pediatrics, emergency.

126. Milwaukee Children's Hospital, pediatrics.
127. South View Hospital, Milwaukee, communicable diseases.
128. Kaulkeolani Children's Hospital, Honolulu.
129. Ingham Sanatorium, Lansing, tuberculosis.
130. Woman's Hospital, Pasadena, obstetrics.
131. Western Oklahoma Tuberculosis Sanatorium, Clinton.

APPROVED RESIDENCIES AND FELLOWSHIPS

Council on Medical Education and Hospitals of the American Medical Association

Hospitals, 587; Residencies, 4,392; Fellowships, 726

The following institutions approved by the Council on Medical Education and Hospitals are considered in position to furnish acceptable training in various specialties as indicated below. Residencies in specialties, as defined by the Council, are straight services of one or more years following an approved internship. A fellowship is a form of apprenticeship which in some cases is indistinguishable from a residency, although it usually offers greater opportunity for the study of basic sciences and research. Ordinarily a fellowship is a university rather than a hospital appointment. Mixed residencies are general hospital assignments following internship. They include services classified as general residencies and chief residencies.

The star (*) indicates hospitals that are also approved for the training of interns. All hospitals on the approved intern list are likewise accredited for general or mixed residencies.
